Expenses

User Manual

Mobile expense tracker
for Android and Wear OS
with KMyMoney integration

Expense created and automatically categorized

1. Voice Input
Simply speak what you spent.
The app understands you.

2. Automatic Assignment
Payee and category are automatically suggested and the expense is assigned.

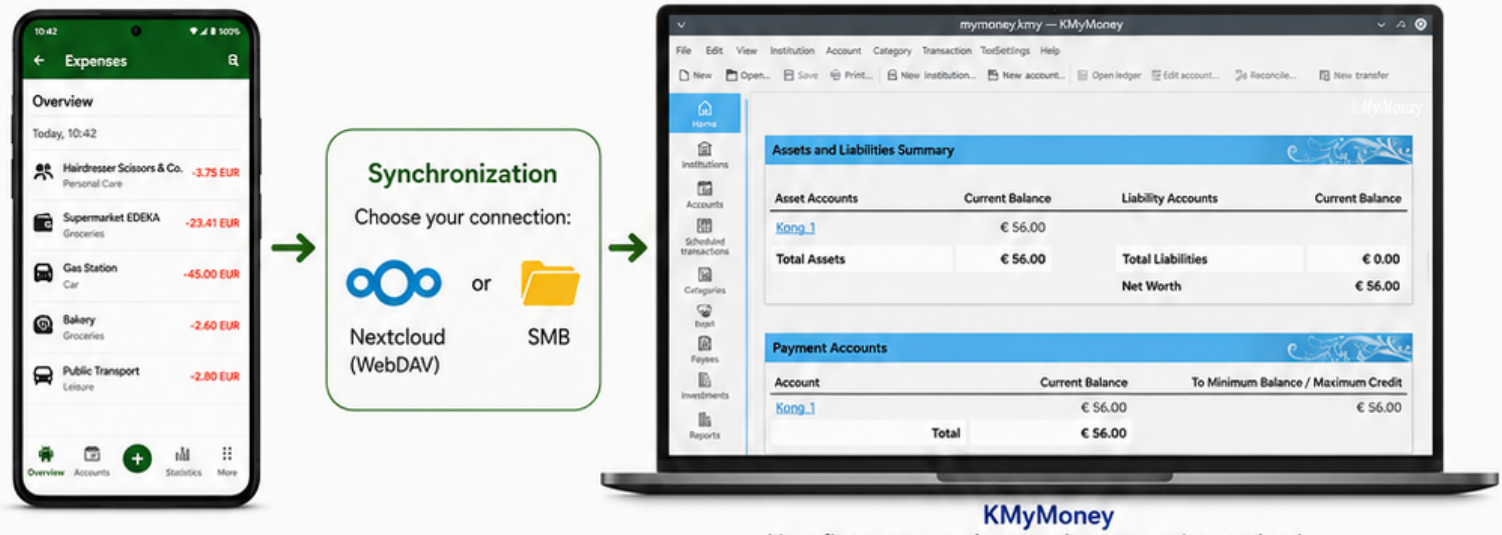

3. Completed Expense
You review, save and keep full control at any time.

Voice Input
Fast and easy expense recording.

Wear OS Support
Enter and overview directly on your wrist.

Automatic Categories
Expenses are assigned to suitable categories.

Synchronization
Secure and flexible via Nextcloud/WebDAV or SMB.

KMyMoney
Your finances at a glance – the way you're used to it.

Version 2.5
Updated: November 2026

1. What is KMySync?

KMySync is a mobile companion to the desktop finance software **KMyMoney**. Use it to record cash expenses, income and transfers on the go – right on your Android phone or a Wear OS watch – and transfer them into KMyMoney later, instead of typing everything in by hand.

Android only: KMySync runs on Android phones from Android 8.0 and on Wear OS watches from Wear OS 3. There is no version for iPhone or iPad (iOS/iPadOS).

Installing: KMySync is available on **F-Droid** – https://f-droid.org/packages/de.spahr.ausgaben/ – and as an APK in the **GitHub releases** – https://github.com/PerFermat/KMySync/releases. The F-Droid version comes without Google services; the watch app and the Play services document scanner are only part of the full version from GitHub. F-Droid signs with its own key, so the two versions cannot update each other: to switch, make a backup first (Chapter 20), uninstall and reinstall.

The app needs no vendor account and no third-party cloud: data is exchanged with KMyMoney through a folder you provide yourself (Nextcloud, WebDAV, SMB/Samba or a folder on the device). There are no ads and no tracking. The one exception is the map for picking a location: it loads its tiles from OpenStreetMap, and only when you open it.

Key terms

- **Booking**: a single money event (expense, income or transfer).
- **Account**: e.g. „Cash“, „Checking“. Every booking belongs to an account.
- **Place (holding)**: *where* an account's cash physically is (wallet, jar, envelope …).
- **Category**: what the money was spent on or received for (e.g. „Groceries“).
- **Alias**: a learned mapping „spoken term → correct payee“ together with account/category.
- **.kmy**: KMyMoney's file format that is exported to and imported from.

2. Your first booking in five minutes

This chapter walks you once through the whole cycle: set up, book, transfer. It names only the straight path and no exception. Everything else – every field, every subtlety – follows in the later chapters.

1. **Set up the connection.** On first start the welcome assistant appears. Choose your language, then **„KMyMoney file (.kmy)“** as the format, and enter your server (Nextcloud, WebDAV or SMB) or choose a folder on the device. **„Test connection“** tells you right away whether it works.
2. **Pick your KMyMoney file. „Choose .kmy“** lists the files in the folder you configured. Take the one you work with on the desktop.
3. **Import your accounts. „Import accounts“** lists the accounts in that file. Tick the ones you need while out and about – usually a cash and a checking account. **„Done“** closes the assistant.
4. **Record your first expense.** Tap the round **+** button at the bottom right. Enter the amount, pick payee and category from the list, then **„Save as new“**. The booking appears in the list immediately.
5. **Transfer it to KMyMoney.** Tap the **export symbol ⬇** in the title bar. The app fetches your .kmy from the server, writes a backup, adds the new bookings and puts the file back. On the desktop you then open it as usual.

That is the entire cycle. From now on only steps 4 and 5 repeat: record while you are out, export when it suits you. Each booking is transferred exactly once.

No KMyMoney file? In the assistant pick the format **CSV** instead of .kmy. The app then exchanges one CSV file per account. Everything else stays the same.

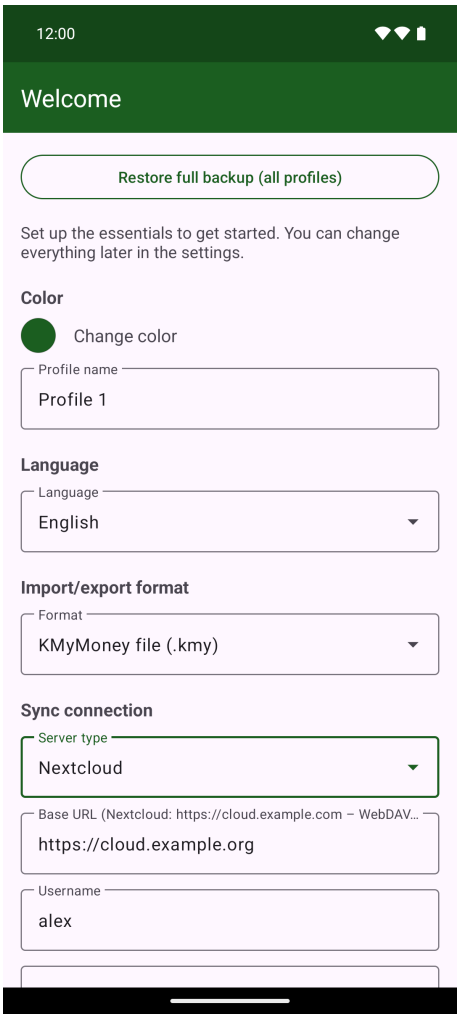

Where to go next: the welcome assistant in detail is in the next chapter, recording a booking in Chapter 8, syncing with KMyMoney in Chapter 18, and every single setting in Chapter 20.

3. Getting started

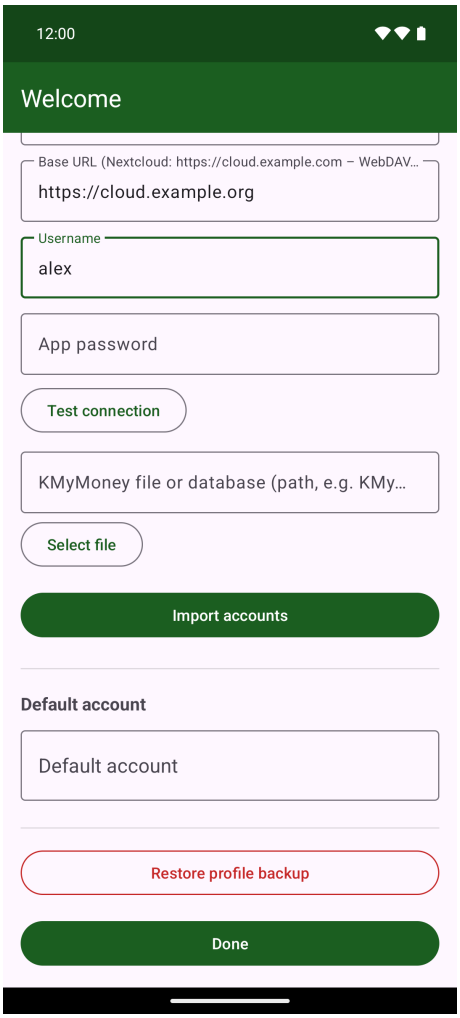

Welcome assistant on first start

As long as **no account** exists yet, a slim **welcome assistant** appears automatically when the app starts. It bundles the most important starting points in one place and can only be opened automatically (no menu entry).

- Choose the **language** (takes effect immediately).
- **Import/export format**: CSV, „Read .kmy, export CSV“, KMyMoney file (.kmy), KMyMoney database (SQLite) or „Read SQLite database, export CSV“.
- **Synchronisation**: server type, URL, user, password – with **„Test connection“**; in .kmy mode also **„Choose .kmy“**. If the file is encrypted, import the **GPG key** or store the **database password** right here as well (chapter 18); if it is missing, the app asks for it during the import.
- **„Import accounts“**: the same selection dialog as „Add account“, right here in the assistant.
- **„Done“** closes the assistant. All further settings can be reached at any time from the menu afterwards.

Language, format and synchronisation

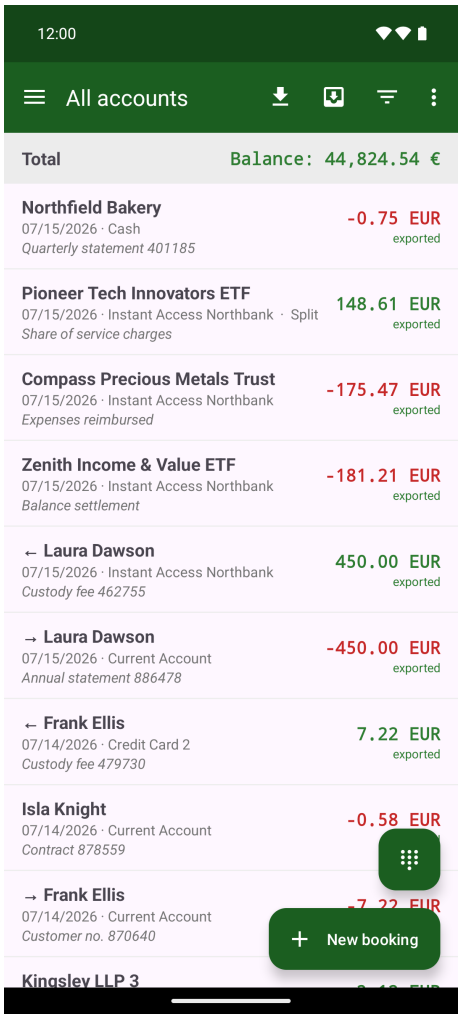

„Import accounts“, default account and „Done“

Important – an account first: create at least one **account** – in the assistant via **„Import accounts“** or later in the account drawer (☰ top left) via **„Add account“**. The **default**

account and the options that depend on it (e.g. places per account) can only be set **once accounts already exist**.

All settings in detail – language, number format, currency, server connection, export mode, default account, alias names, app lock, backup and more – are explained in the **„Settings“** chapter at the end of the manual (Chapter 20). They are reachable any time via the **⋮ menu** at the top right, entry **„Settings“** at the very bottom.

4. The main screen

Main screen with title bar, balance line and booking list

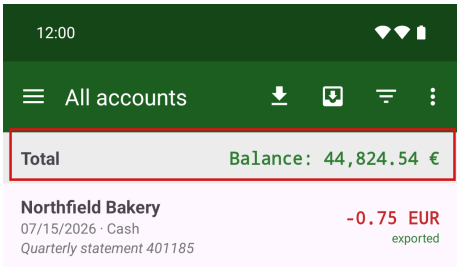

The main screen shows the green title bar at the top, the **balance line** below it, and then the list of bookings. The action buttons are at the bottom right.

Balance line (tap to cycle)

The coloured line below the title bar shows a balance. **Tapping** it cycles through, in order:

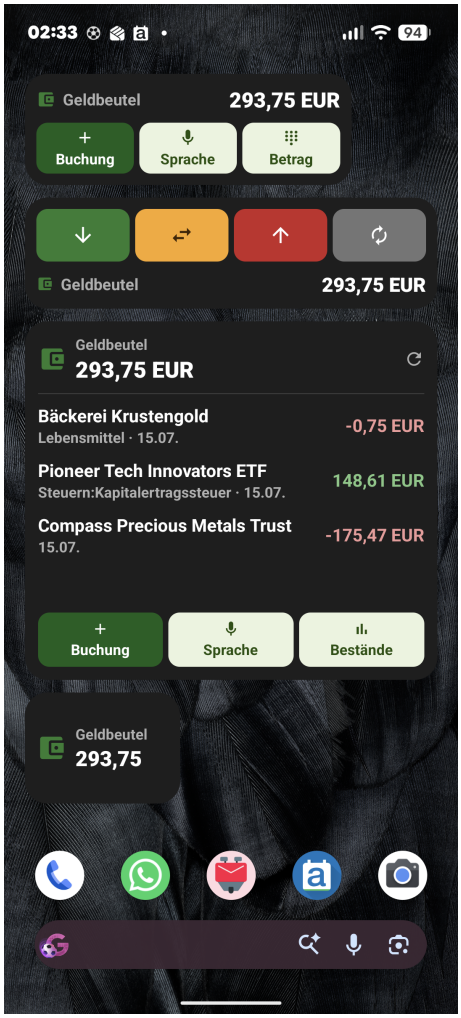

- **Account**: balance of the currently selected account (only when a single account is selected).
- **Total**: sum of all accounts. An account in a **foreign currency** counts here with its balance × the exchange rate from KMyMoney, i.e. in the file's base currency; in its own view it stays in its currency. The same applies to the group total and the net worth history in the analysis.
- **Net worth**: all accounts + current portfolio value (only after a portfolio was imported).
- **Places**: balances of the account's individual cash places.
- **Filtered**: sum of the currently filtered bookings (only when a filter is active).

A green amount = positive/credit, a red amount = negative.

Balance line; tapping cycles through

Home-screen widget

All four widget sizes: medium, type, large and small

For the launcher there are four widgets. All of them show the **default-place** balance (default account → default place), and tapping the balance opens the app.

- **small** (2×1): the balance only.
- **medium** (4×2): the balance and three quick actions – booking, voice, amount.
- **large** (4×4): a balance header with refresh, the most recent bookings and the action bar.
- **type** (4×2): like on the watch – three coloured icon buttons for income, transfer and expense, plus a grey switch button, with the balance below.

What the buttons do

On the medium and large widget the buttons launch „New booking“, voice entry, amount-only entry or Holdings – each of them inside the app.

Refreshing happens when the app is opened and at regular intervals.

The **type widget** goes one step further: a type button **starts speech recognition immediately** and creates the booking directly, without opening the app (only the system voice dialog appears). The grey **switch button** cycles through the chosen account and its places; the balance and the target of the next booking follow that selection.

5. Symbol and control reference

This overview explains every symbol in the app and what it does.

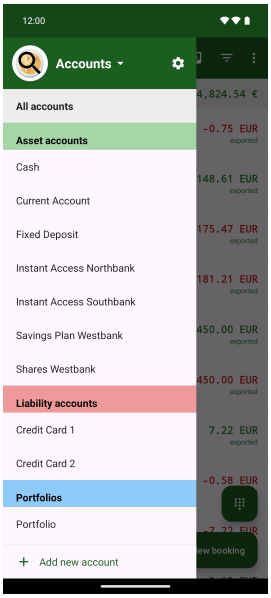

Symbol	Name	Meaning / function
☰	**Menu / account drawer**	Top left. Opens the side drawer with all accounts, portfolios and „Add account“.
←	**Back**	Top left on sub-screens. Returns to the previous screen.
⬇	**Export / synchronize**	Title-bar symbol (down arrow, download style). Starts the sync: writes new bookings into the .kmy or uploads them to the sync target.
▽	**Filter**	Funnel symbol. Opens the filter by payee, category and amount.
▮▮	**Analysis**	Bar-chart symbol. Opens the graphical analysis.
⋮	**More items**	Three dots (overflow). Contains „Categories“, „Holdings“, „Budget“, „Scheduled“ and – **at the very bottom** – „Settings“.
✚	**New booking**	Round button at the bottom right. Short tap: record a booking. **Long press: voice input.**
⊞	**Silent amount entry**	Keypad symbol (only when location is enabled). Type just the amount; the payee is resolved via your location.
↑	**To top**	Small arrow. Jumps to the top of the booking list.
★	**Preferred alias**	Marks a preferred alias in the alias list (considered before bookings).
→	**Alias mapping**	In the alias list: „spoken term → correct payee“.
→ / ←	**Transfer**	In the booking list: → outgoing, ← incoming transfer (shows the counter-account/payee).
Split	**Split booking**	Marks a booking that is split across several categories.
exported	**Exported**	Small green hint: this booking has already been exported.
● red/green	**Amount colour**	Red amount = expense/negative, green amount = income/positive.

Note: the title-bar symbols come from the Material Design set; their meaning is described above. Depending on space, some items appear in the „ ⋮ “ overflow menu.

6. Accounts and the account drawer

The account drawer is the list of your accounts. ☰ at the top left opens it; a tap on an account shows its bookings, a long press fetches it afresh from KMyMoney. Day to day that is all you need. The rest of this chapter explains how to group, search and sort accounts.

- Open it via the ☰ symbol at the top left, or by swiping in from the left edge.
- **„All accounts“** shows all bookings together; a single account filters the list to it.
- **Long press on an account**: import/update that account from the .kmy.
- **Long press on „All accounts“** – or pull down in that view: reloads **everything** (accounts, portfolios and scheduled transactions) in one pass.
- **Portfolios** sit at the bottom under the „Portfolios“ heading and behave just like accounts: a short tap opens the portfolio view (the selected portfolio stays highlighted), a long press updates it.
- **„Add account“** (at the bottom): loads the .kmy and offers the contained accounts for selection.

Account drawer with accounts, portfolio and „Add new account“

Account groups

Besides the **account kind** (asset, liability, portfolio) there are **account groups** for your own ordering – „Favourites“, „Joint“ or „Savings“, say. An account may sit in any number of groups; the grouping by account kind is unaffected.

Choosing a group

Tapping the „Accounts“ heading drops the groups down as a list; the one in force carries a **tick**. The drawer then lists only its accounts, and the top row carries the group name instead of „All accounts“.

The choice applies **app-wide**: the booking list, the balance bar and the holdings view all follow it. In the balance bar the group appears as an additional first page; „Total“ still means all accounts.

Where the groups come from

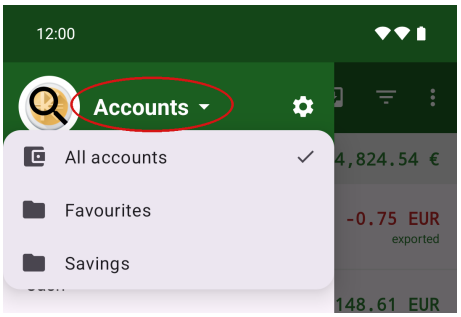

Each row carries the mark of its origin: a **folder** for groups you created, a **bank building** for those from the institutions block of the .kmy (e.g. „Volksbank“), a **star** for the „Favourites“. The latter two merely mirror the file – only the import writes them, they cannot be edited by hand.

The **„Favourites“** come from the accounts marked as preferred in KMyMoney (its account dialog, „Preferred account“). They sit at the very top of the picker, are rebuilt on every import, and their name follows the language of the app.

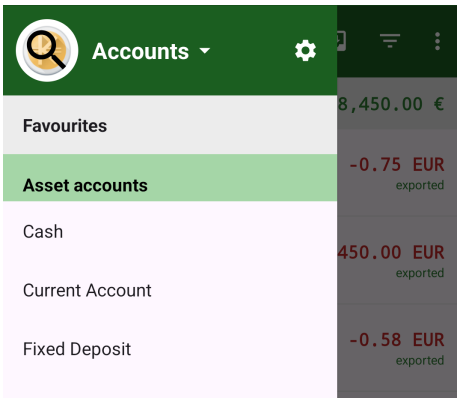

When a group disappears

Removing the **last account** from a group (or deleting that account) makes it disappear without asking – there are no empty groups. That is also how you get rid of a group again. Once no account is preferred any longer, the „Favourites“ likewise disappear.

Groups holding nothing but **closed** accounts no longer show up in this picker. They stay selectable in an account's „ ⋮ “ menu so they can be revived.

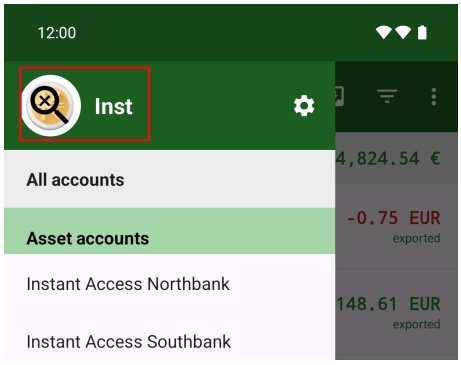

Tapping „Accounts“ opens the group selection

Afterwards the top row carries the group name

Searching accounts

The search field takes the place of the „Accounts“ heading

A **magnifier** sits on the kMyMoney emblem at the top of the drawer. Tapping it opens the keyboard, and for the duration of the search your input takes the place of the „Accounts“ heading. What you type filters the account list instantly by part of the name – „kasse“ thus also finds „Sparkasse“ and „Barkasse“.

Closing the keyboard puts the heading back in its place – but the term **stays in effect**, so the list still shows only the matches. The magnifier now carries a small cross to signal that a filter is on; tapping it lifts the search.

The search stays inside the chosen account group and is never stored. It also ends by itself as soon as you pick an account, close the drawer or leave the app.

Sorting and managing accounts

The **gear icon** next to „Accounts“ opens a view of its own. Unlike the drawer it also shows **closed accounts**, in grey, each with its balance on the right.

Changing the order

Drag the handle to sort accounts within their account kind. The order applies everywhere accounts are listed – including the pickers while recording a booking. Drag a **whole account kind** and its accounts collapse for the duration of the drag, leaving only their number; that way even a large block reaches its place in a few movements.

Putting an account into a group

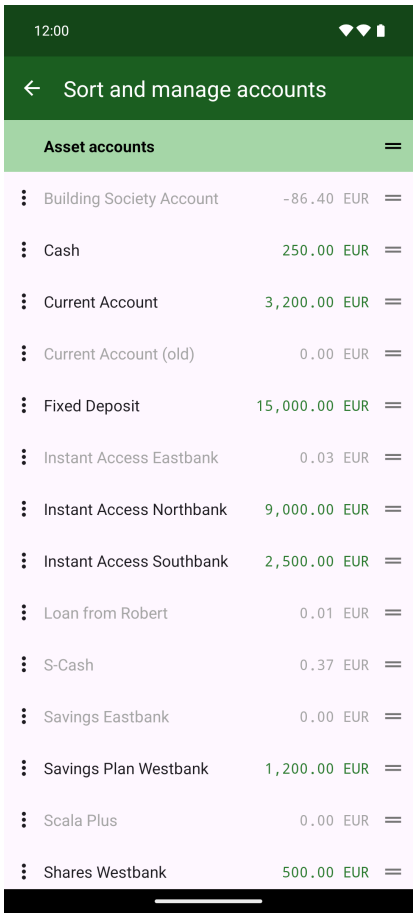

The **„ ⋮ “** on an account row opens your own account groups as a **tick list**. The tick says whether the account sits in that group; set and clear as many as you like, nothing is written until **„OK“**. On top there is a free field for a **new group** – typing into it ticks its box by itself.

Closing and reopening an account

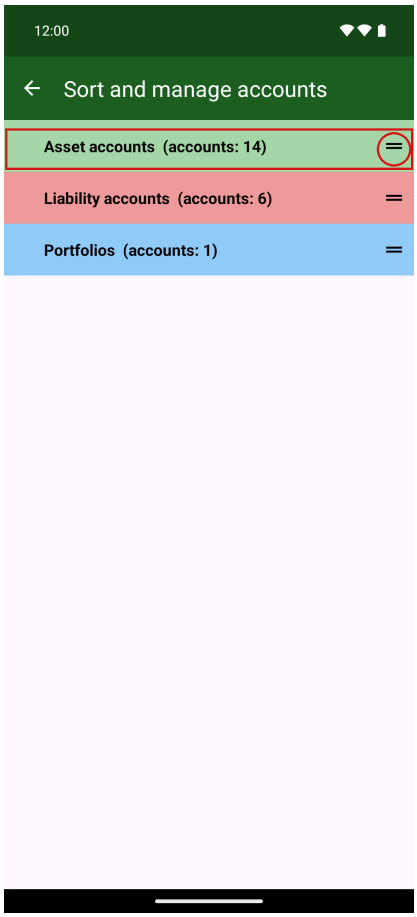

The same tick list carries, next to „OK“, a **„Close account“** (or „Reopen account“) button; it applies the ticks along the way. Closing is offered only at a **balance of 0**. If a closed account regains a balance on import, it reopens by itself – unless KMyMoney itself lists it as closed. **Kept in step with KMyMoney**: an account closed in KMyMoney arrives closed in the app – in the account selection on import it is listed last with „(closed)“. The other way round, in .kmy mode the next export carries over to KMyMoney what you close or reopen in the app.

Special case: groups from the .kmy

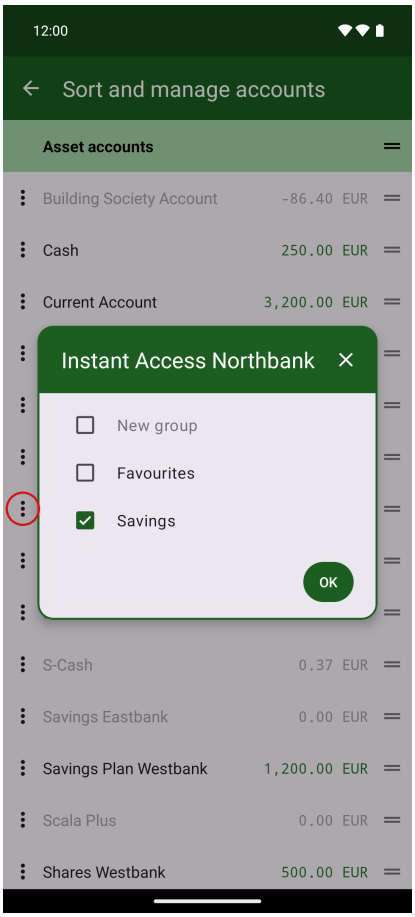

Banks and favourites are not in the tick list. Type one of their names into the free field and the dialog stays open with a note, writing nothing – an assignment by hand would be gone again at the next import anyway.

Management also shows closed accounts, greyed out, with balance

Dragging an account type folds its accounts away

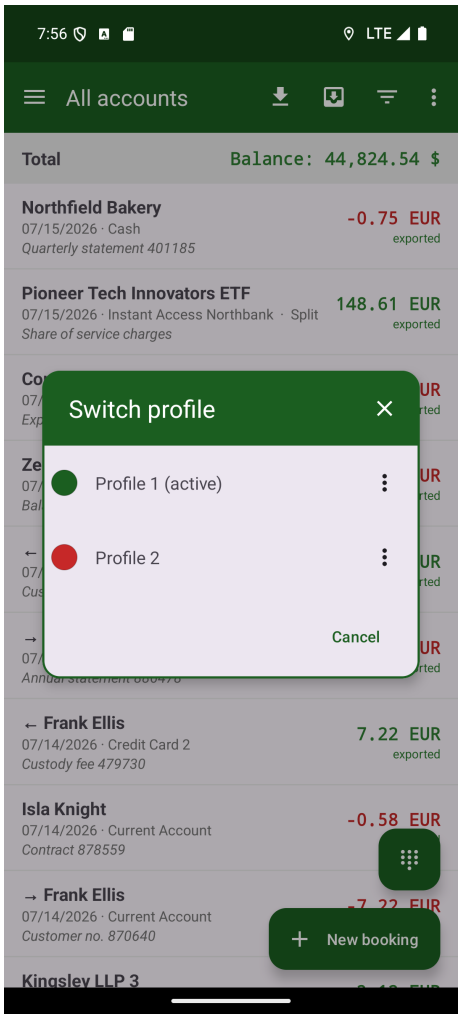

„ ⋮ “: tick groups or create a new one

7. Multiple Profiles

A **profile** is a fully separate set of data: its own accounts and bookings, its own server connection, its own currency, number format and accent colour. Handy for keeping personal and business separate, or when several people share the same device. The welcome assistant creates the first profile automatically on first start; further ones are added through the settings. Only **one** profile is ever active.

Switching profiles

1. Menu ⋮ → **Switch profile** opens the list of all profiles; the active one is marked „(active)“.
2. Tap another profile to switch to it instantly, without restarting the app.

List of all profiles – a tap switches instantly

Creating a new profile

In the **settings**, „**Create new profile**“ adds another profile – the same short assistant as on the very first start (Chapter 3): language, server, done. The new profile becomes active right away.

Editing a profile

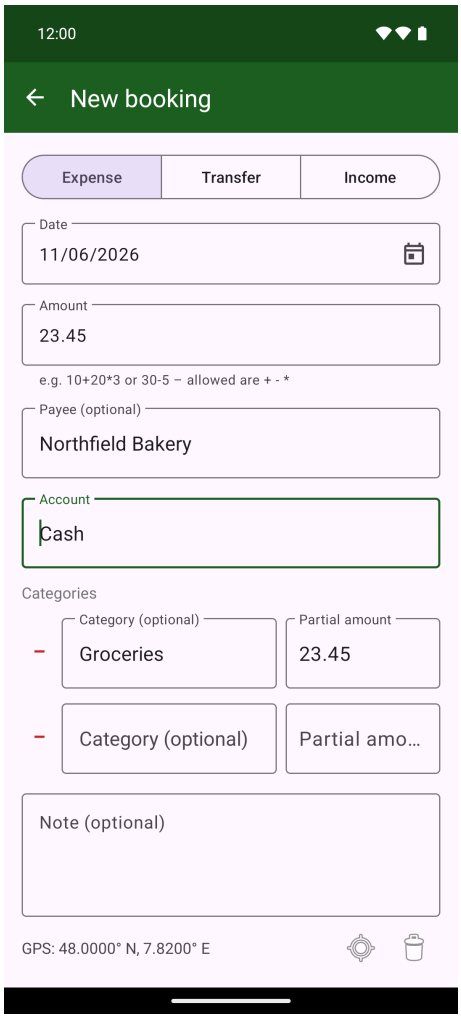

A **long press** on a row in „Switch profile“ – or its ⋮ menu, entry „**Edit profile**“ – opens the full settings screen for that profile: currency, number format, dividends, budget, places, alias names, deleting/closing accounts, backing up and resetting the profile. If the profile is not active yet, the app switches to it first.

Rename, change colour, delete

The same ⋮ menu also offers „**Rename**“ and „**Change colour**“ (the accent colour of buttons and the toolbar, for this profile only). „**Delete**“ removes the profile along with its bookings and accounts irreversibly – available only from the second profile on, one must always remain.

Device-wide instead of per profile are language, dark mode, app lock and the reminder for due bookings – these settings apply to all profiles alike.

8. Recording a booking

Booking editor with type switch, amount, payee and account

Tap the round **+** button. The booking editor opens. An ordinary expense is recorded in four steps:

1. Type the **amount**.
2. Pick the **payee** or type a new one.
3. Pick the **category** – usually it is already there.
4. **„Save as new“**.

Account, date and place are pre-filled and need attention only if something else should apply. The rest of this chapter explains the fields one by one.

Picking a value – the same everywhere

Payee, **account**, **category** and **place** fields are display, list and search box in one – in the booking editor just as in transfers, reconciliation, the filters, the alias editor, the settings and the analysis.

- **Entering the field**: the current entry steps aside and stays on only faintly; the full list opens.
- **Deleting characters**: the list widens again. Empty the field and everything is back.
- **Typing**: the list narrows as you go. Matches are found anywhere in the name and regardless of case – "kasse" finds "Sparkasse".
- **Tapping an item**: it goes into the field and the keyboard closes.
- **The Done key** (bottom right on the keyboard): finishes the entry and closes the keyboard without you leaving the field. If typing leaves exactly **one** match, it is taken – "visa u" is enough for "Visa Urlaub". With several matches the same rule applies as when leaving the field.
- **Leaving without a choice**: the previous entry returns.

A **new payee** may be created this way: type a name that does not exist yet and it stays. **Account, category and place** have to come from the list – an invented name is replaced by the previous one when you leave the field. New accounts arrive through the import, new places are created in the settings.

Account fields put what you are most likely to need at the top: first your **favourites** (star), then the accounts of the currently selected **account group** (the group's own icon), then all the rest with the icon of their account kind. Your own account order is kept within each block.

What the app suggests for you

If the location is known, the payee list heads with a few nearby payees marked by a bearing arrow – as soon as you start typing, this suggestion disappears again.

Pick a payee and the app fills in the matching category right away. Change a category row yourself and it stays put, no longer overwritten.

Optionally (switch on in the settings under „Use amount for payee suggestions“), the typed **amount** alone can suggest a nearby payee, if it clearly matches one.

Arithmetic in the amount field

The **amount field** accepts a small **calculation** instead of the system keyboard (e.g. *10+20*3* or *30-5*) – handy when splitting a bill or offsetting several items.

Fields and controls

- **Type switch**: Expense · **Transfer** · Income. Sets the kind of booking.
- **Amount**, **payee** (optional), **account** (chosen from existing accounts).
- **Date**: pre-filled with today; the **„Today“** button quickly sets the current date.
- **Note**: free text. With location enabled it automatically contains „GPS: lat, lon“.
- **Place** (only for expenses/income created in the app): which cash place the booking is credited to.
- **„Exported“ toggle**: marks whether the booking has already been exported.

The payee may be left blank – as in KMyMoney, where it was never mandatory. Where it is missing, the booking list, the widget, the budget and the category breakdown show the **category** in its place. If the amount is split across several categories, they show **„Split transaction“** instead, because otherwise only the largest of the categories would be visible and nothing of the split. If the category is missing too, they show **„*** UNASSIGNED ***“** – the same text KMyMoney uses in this case. There as here it is **display only**, not a category that actually exists.

Saving

- **Save as new**: creates a new booking.
- **Update**: saves changes to an existing booking.
- **Delete**: removes the booking.

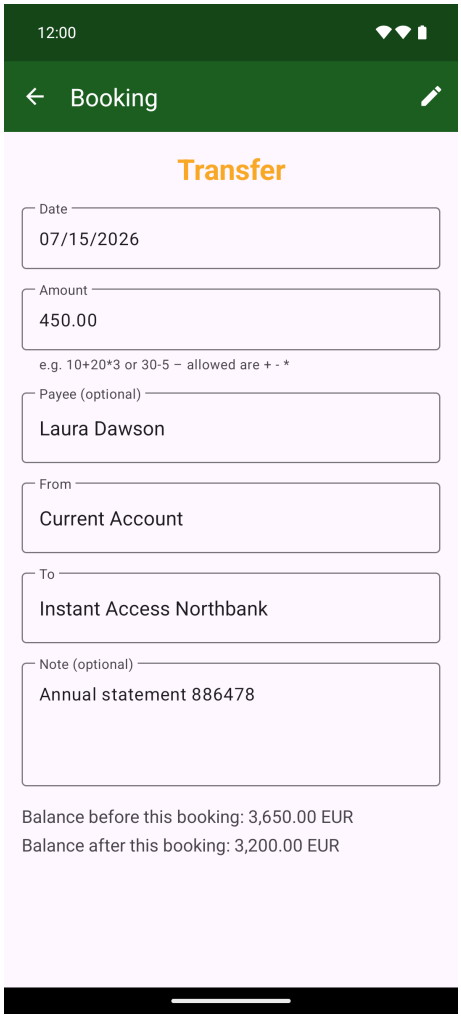

Date prompt when copying: if you open an existing booking, leave the date unchanged and „save as new“, the app asks whether the old date or today should apply.

Split booking (several categories)

In the „Split categories“ section you can enter several categories with partial amounts. With one category the total and category amount are linked; with several, the sum must equal the total. Partial amounts may be negative. Split bookings exist **only in .kmy mode**: KMyMoney's CSV import accepts just one category per booking. When writing via CSV, there is only one category row; templates, schedules or aliases with several categories then prefill no category.

Transfer

Choose the type „Transfer“, then the From and To accounts plus an optional payee. This creates a linked booking in both accounts (marked → or ← in the list). You can also choose a **from-place** and a **to-place**; then the respective place journal is updated (from-account −amount, to-account +amount). Both fields are preset with the **default place** of the respective account; „no place“ leaves that side's journal untouched. Editing or deleting the transfer rolls the place movements back.

Detail view of a transfer with balance before/after

Tags

KMyMoney has **tags**: freely maintained keywords such as „Holiday“ or „Tax“, any number of which a booking may carry. Below the note field there is a **„Tags“** row for them.

The **pencil symbol** opens a window listing every tag; a field below adds another one, the **bin symbol** clears all of them at once. Only what already exists in KMyMoney can be entered.

Tags work the same for **expenses, income and transfers**. If the app does not know any tags yet – in CSV mode without a KMyMoney file, say – the row does not appear at all.

Reconciled bookings

Once you have **reconciled** a booking in KMyMoney, that is, confirmed it against the bank statement, it belongs to a closed period. KMySync adopts this status when it reads the .kmy file and from then on only displays the booking: in the list it carries a small lock, and the form offers neither „Update booking“ nor „Delete“. It can only be changed in KMyMoney. It remains usable as a template: „New booking“ creates a copy and leaves the original untouched. If you undo the reconciliation there, the booking is editable again after the next import; bookings that are merely „cleared“ stay editable anyway. If a booking was reconciled only after you had changed or deleted it in the app, KMySync does not transfer that change and tells you so. Import the file again and make the change in KMyMoney.

9. Securities - Portfolio

The portfolio displays your securities from KMyMoney and allows you to record buys, sells and dividends – both manually and through automatic PDF recognition of bank statements. This chapter covers the portfolio view and its features.

The portfolio only exists when the app **reads from the KMyMoney file** (.kmy mode or „Read .kmy, export CSV“) – securities only come from reading the file. Entering buys, sells and dividends (manually or from a PDF) works only in **.kmy mode**, because CSV export cannot write securities bookings back. In plain CSV mode, the portfolio section is missing from the account drawer.

Securities bookings: buys, sells and dividends

The portfolio supports recording **buys, sells and dividends** for securities – but only for **securities you have already set up in KMyMoney**. The app does not create new securities.

Two ways: You can either **record a transaction manually** in the booking editor (date, shares, price, fees, taxes) or let the app try to recognize the values automatically from a **PDF statement from your bank**. For manual entry, simply fill in all fields as usual and save.

The portfolio view

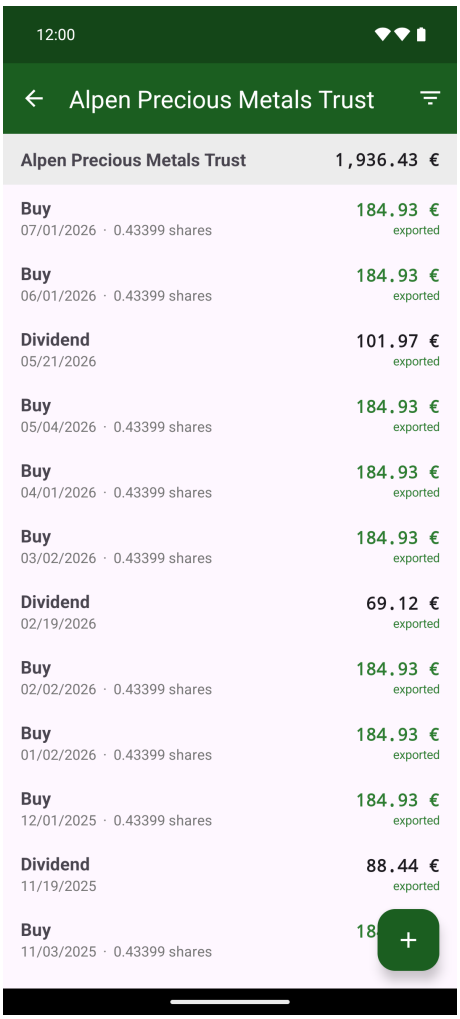

Portfolio view: securities with quantity, price and current value

After importing a KMyMoney investment account, the **portfolio** appears in the account drawer. The view is structured like a regular account view – same title bar, same drawer, same filter – and shows for each security **quantity × price = current value**. Next to the price stands its **date**, e.g. „12.3456 × 31.50 (11/6/26)“ – so you see at once whether the app has an outdated price. Fully sold securities are hidden.

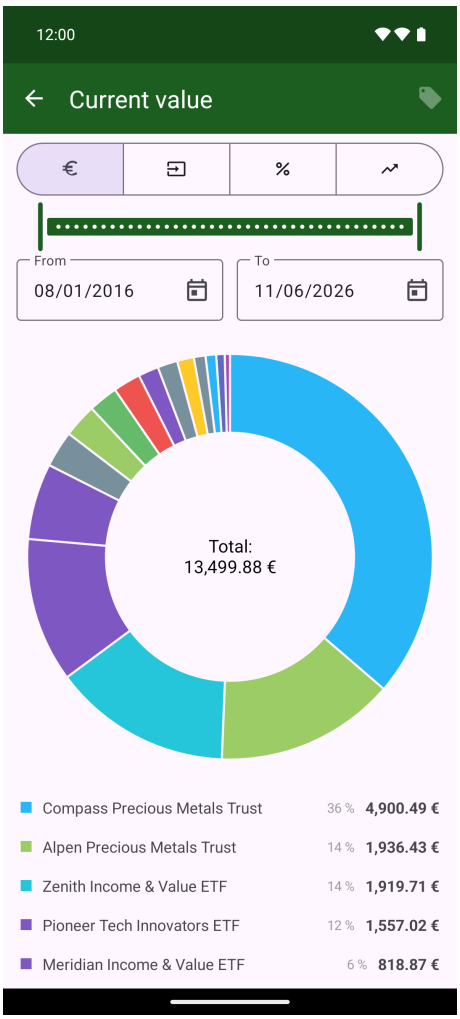

Securities in a foreign currency: a security that KMyMoney keeps in another currency – say a dollar fund in a euro file – is converted by the app into the file's base currency using KMyMoney's exchange rates, each time with the rate of that day. The row shows the original price with its currency („1 × 83.49 USD“), the value on the right is in euros; so the portfolio total, net worth and net worth history add up. Buys and sells are taken over with the euro amount KMyMoney booked. If KMyMoney has no exchange rate, the app uses the unconverted amount.

The **balance line cycles through on each tap**: portfolio value → buys → sells → dividends → **net invested** (buys − sells − dividends) → **gain/loss** (in colour, with percentage). Sells and dividends only appear if there are any. The portfolio value is tracked separately and also appears as „Total assets“ in the balance line of the main screen.

Tapping a security opens its **transactions in full screen** – buys in green, sells in red, dividends in neutral – with the same figures for that security, a filter for buys, sells and dividends, and a date slider starting from the first purchase.

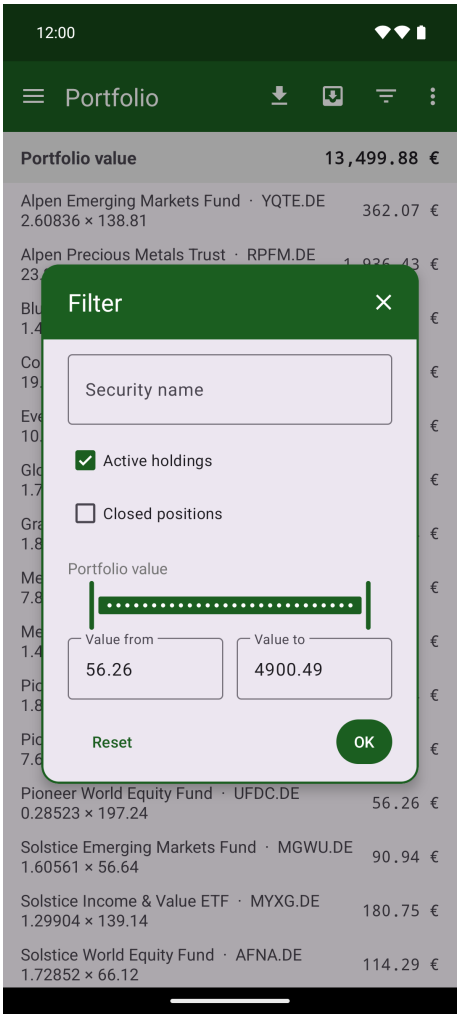

Transactions for a security, here buys and dividends

Portfolio analysis: symbol switcher, date range filter and pie chart

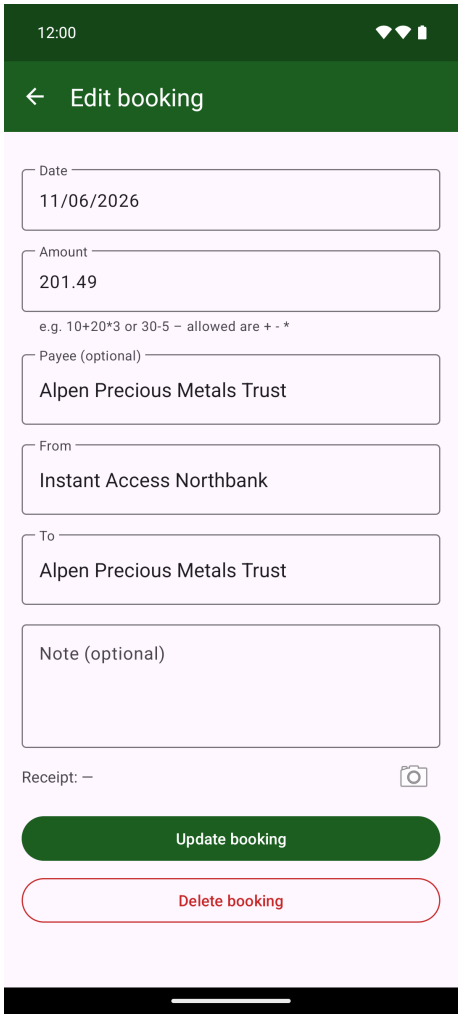

Filtering positions

The **funnel** ▽ in the portfolio toolbar filters like in the booking list: by name, by value – and additionally whether **active holdings** and/or **closed positions** (zero shares) are shown. Default: active only.

Filter: name, value range, active and/or closed positions

Opening a securities booking

An opened securities booking: only note, tags and receipt can be changed

A securities purchase also appears in the booking list of the settlement account – as a transfer between that account and the security. When you open it, **amount, payee, accounts and date are locked**. Why: **quantity and price** belong to this booking but only exist in the KMyMoney file. The app doesn't know them – if it could rewrite the booking like a regular transfer, the securities purchase in your file would become a bare transfer and destroy the portfolio there.

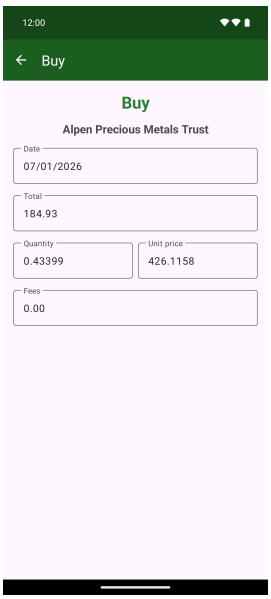

What can be changed are exactly the three things KMyMoney doesn't need itself for such a booking: the **note**, the **tags** and the **receipt** – your bank's statement as a PDF, for instance. On the next export the app adds them to the existing transaction without rebuilding it: shares, price and type of movement stay untouched. That way you find the statement again even after re-reading the portfolio.

Deleting works – unlike editing

„Delete“ is available here, and it takes the associated **portfolio transaction** with it; otherwise a transaction without a cash booking would remain in the portfolio. Unlike editing, deleting removes the **whole** transaction at once, nothing stays half-finished.

If the booking is already in the KMyMoney file, it will be removed **there** too on the next export. **Undo is not available.**

A **short tap** on a transaction shows the numbers behind it: for **buy** and **sell** number of shares, share price, amount, fees and the resulting total (charge on buy, credit on sell); for **dividends** the quantity held, gross dividend per share, gross amount, taxes/levies and net amount; for **in-** and **out-bookings** the quantity. **Fees** only appear after a fresh portfolio import – otherwise the line is missing.

Security booking: details on quantity, price and fees

For **inflows** and **outflows** KMyMoney only knows the quantity, not the cash value. A **long tap** on such a line opens a dialog to enter the value manually (using the same calculator keyboard as elsewhere in the amount field) – it then counts as a purchase or sale at cost price and gain/loss and survives a fresh portfolio import.

Analysis (pie chart)

The **„Analysis“** menu opens a **pie chart** of the securities, styled like the categories page. Tapping a segment shows the name and amount of that security.

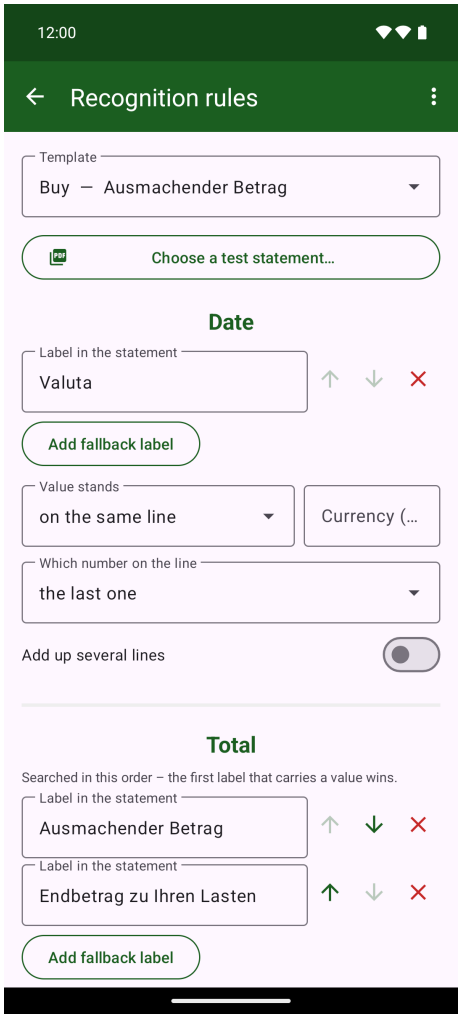

At the top a **symbol switcher** chooses the view: current value, net invested, dividend total or gain/loss. Below, a **date range filter** narrows the analysis.

An icon in the menu bar shows or hides fully sold securities (hidden by default).

Read PDF statements automatically

The portfolio view can read securities statements as a PDF and automatically prepare transactions from them. The **first time** you manually check and confirm the values – the app **learns** the rules for that bank while you do. Then on subsequent statements from the same bank the app automatically fills in the values. How the recognition rules work in detail and how to adjust them is covered in the next chapter.

10. Recognition rules for PDF statements: learning and managing

The learned recognition rules of a portfolio

The PDF recognition feature (enabling under **Read PDF statements**) works on a simple principle: you show the app **the first time** where the values are located, and the app **remembers the rule** for all subsequent statements from the same bank – until you change it.

The first statement from a bank: You download a PDF, open the portfolio and tap „Read PDF“. The app tries to recognize the values (date, shares, price, fees, taxes etc.) automatically. It shows you the result for **review** – just like manual entry. Each value you enter or correct is learned: the app records **where in this PDF the values were** (which label, which line) and how you named the values (which category, which label at the bank). After you confirm („Store“), the app applies the rules immediately to the same PDF – as a **test**. If the result fits, it saves the rules and you can book. If not, it opens the **rules page** right away, where you can see and correct the just-learned rules.

Subsequent statements: The next PDF from the same bank, the app **automatically fills in** all values – you only need to review and can book directly. Should the bank's format change (new columns, different labels), review the values and confirm with „Store“ – the app updates the rules automatically.

Adjust recognition rules: If a learned rule no longer fits or you want to correct it manually, open the portfolio and tap ⋮ → **Recognition rules**. You see all the rules learned so far, sorted by bank. Tapping a bank shows its rules: for each field (date, amount, fees etc.) there is the **learned label** (what the bank calls the row), the **position** (which row, which column), whether there is a **fixed fee** per trade, and further details. You can **delete** each rule

individually so the app learns it fresh the next time from that bank – or you edit the rule and manually adjust the label, position and options.

Share and import rules: What your app has learned about a bank can be passed on: ⋮ → **Share rules** on the rules page sends this portfolio's rules as a small JSON file – by mail, messenger or into the files app. It holds only the labels and reading rules, **no amounts and no securities**. The other way round, ⋮ → **Import rules** takes such a file into the open portfolio and **replaces its previous rules** – a prompt names beforehand what the file holds. That way you get the rules for your bank from someone who banks there too, without typing a single label yourself. And if one of your statements is not recognised, you send the rule it hinges on instead of describing it.

Picking values from a table

Tapping the date field in the form, or a label field on the rules page, offers the entries the app found – **each by both routes where both exist**: via the label beside the value and via the column heading above it. So if „Value date“ sits as a heading above the date and „as of“ beside it, both lines appear, the column variant stating how many lines below it reads. Whatever you tap is stored exactly like that – the app does not decide for you which label the bank will keep in its next statement.

Values inside a table

Some banks do not put the figures behind a label but **under a column heading**. The data row then starts with a number and carries no label of its own. For such statements **„on one of the lines below“** means: the next line that carries a value at all – up to three lines away. That skips a second header line, which some banks insert. If the search gets stuck on an in-between line that happens to carry a number, pick **„exactly 1, 2 or 3 lines below“** instead.

A table row often carries several entries of the same kind – the booking day first, the value date next to it. Which one is meant is set by **„Which number on the line“**; it applies to dates as well. For dates the default „the last one“ still means **the first** entry after the label, out of consideration for older rules – if you want another, pick „the first (table column)“ or „the 2nd from the left“ explicitly.

In the label's column: In a table, counting only works as long as every column is exactly one number wide and none is missing. When the label is a column heading, pick **„the number in the label's column“** under „Which number on the line“ instead: the app then takes the value that sits below (or above) the label on the page. That holds even when a later statement omits a column. The choice is offered only together with „below“ or „above“ – on the same line the label's column would be the label itself.

Values above the label: Some statements print the number first and name it underneath. For those there are **„on one of the lines above“** and **„exactly 1, 2 or 3 lines above“** – the mirror image of „below“.

Help while typing: under „Check statement“, next to the result, sits the button **„Text with line numbers“**. It shows the statement the way the app reads it. That is necessary because its lines are not the lines of a PDF viewer: they come from the word positions, and a visually empty line does not exist there at all. For counting the distance it is the only reliable source.

Multiple categories for fees and yield

Just like in the booking editor, „fees/taxes“ – or on a dividend the „yield“ – can be split across multiple categories. In the entry form the button **„+“** below the line adds another category; the sum of all lines must match the amount above.

The same button sits on the rules page: each sub-line gets its own recognition rule – label, direction, position, just like a normal field. When you say „Store“, the app automatically creates such a sub-rule for each category line whose label it finds in the statement.

If a remainder is left over that does not appear on the statement – for instance a bank fee that some institutions do not print – the app **remembers only this remainder** as a fixed fee, not the whole amount. On the next read it appears as its own, last category line alongside the recognized ones.

A fee not listed on the statement

Some banks charge a fixed amount per trade without listing it on the statement. A rule cannot find it – it looks for a label and there is none. On the rules page, therefore, under **fees** sits a field **„Fixed fee per trade“** with its category.

Whether this amount takes effect is decided by the toggle **„Add multiple lines“**. If the rule finds no fee in the statement the fixed value applies. If it finds one and the toggle is **on**, the fixed value is added. If **off**, the found fee wins and the fixed value is ignored.

The **total amount** has a corresponding toggle: **„Fixed fee is already included in the total amount“**. Off = the amount debited is higher by the fee than the number on the statement – on a sale the credit is lower by it – and the app adds it up. On = the total amount stays as it is.

Recognized automatically: If you enter a total amount and a fee during entry, **both** of which do not appear on the statement, the app tries the difference – i.e. the amount without the fee. If it finds it, it learns the label and enters the fee as a fixed trade fee. This is the only value the app does not read but deduces; the prompt mentions it explicitly with the amount.

11. Recording quickly: voice, location, receipts

This chapter collects the ways a booking can be created with just a few taps: **speak** it, type only the **amount** and let the app guess the payee from your location, attach a **receipt**, and teach the app a mapping as an **alias**.

Voice input

Long press the **+** button to open voice input. Say, for instance, "hairdresser 20 euros": the app looks for a matching template (payee, account, category, booking type) and opens it with today's date and the spoken amount.

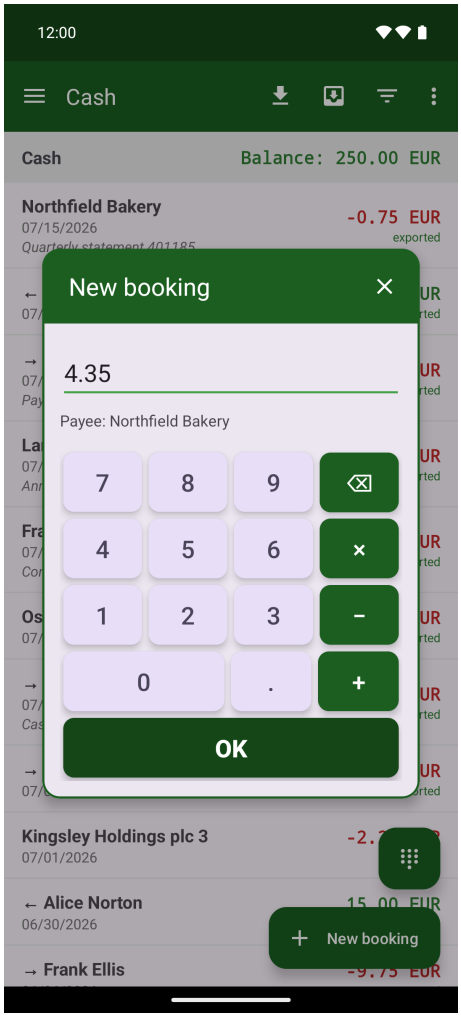

Nearest payee

If there are several payees with the same name (e.g. „REWE Location 1“ and „REWE Location 2“) and the location is known, the app picks the **geographically nearest** one.

Amount only (number pad ⊞)

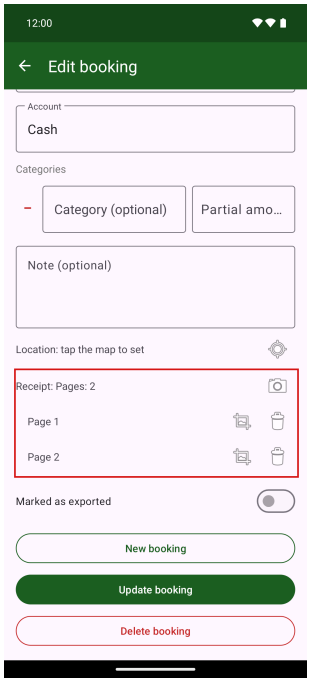

With location enabled, a number-pad symbol appears at the bottom. Type just an amount: the app looks for a matching payee at your current location and shows it before you save.

If several known payees are near you (petrol station and car wash), the **amount** helps guess which one – as you type, the suggested name changes. Tapping the name cycles through the other candidates and finally „no payee“. This requires the switch **„Use amount for suggestions“** (off by default) – without it, only distance counts.

Amount-only entry: the payee is found via location

Receipt photos

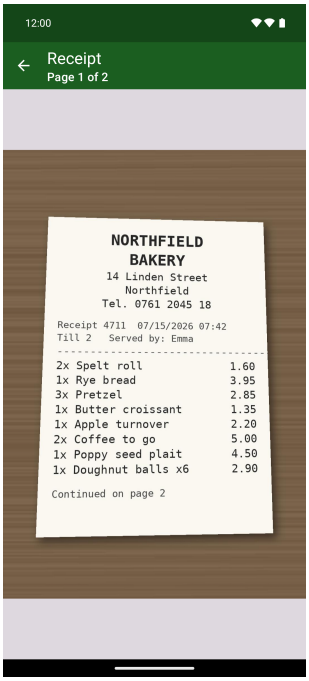

While editing, each page gets its own row with crop and delete

In the booking editor, the **„Receipt“** button attaches a photo (camera or gallery) or a **PDF document** – multiple pages if needed, for a long receipt for instance. This works for every booking type, including transfers.

Images are stored privately and uploaded in the background to the **„Receipts“** folder of your sync folder; ones taken offline follow once a connection is available again. The reference stays in the note, so the app finds the photo again even after a fresh import.

A built-in **viewer** shows the pages: swipe to flip through, pinch or double-tap to zoom in on fine print.

Delete a booking and its receipts disappear only on the **next app start** – not immediately, so „Undo“ right after deleting still brings the receipt back.

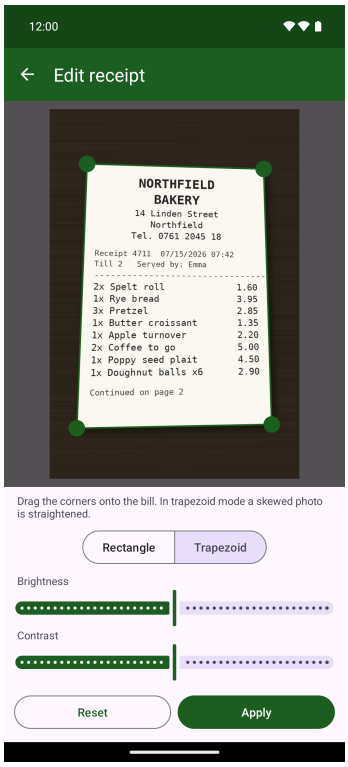

The built-in viewer counts pages too: „Page 1 of 2“

Document scanner: in the variant with Google services (GitHub download „full“), the camera opens the Play services document scanner. It detects the edges of the receipt, straightens it and captures several pages in a row. Without Play services, and in the F-Droid variant, the usual camera is used.

Exporting the receipts of a filter

In the (⋮) menu of the booking list, **„Export receipts“** packs all receipts of the currently filtered bookings into a **ZIP file** with readable file names (date, payee, amount) – handy for a tax advisor, for instance. The entry only appears when a filter is set.

Cropping and straightening receipt photos

Editing: four corner points, „Rectangle“/„Trapezoid“, brightness and contrast

Right after taking the photo, the app asks whether you want to **edit** it. With „Keep as is“ it stays unchanged; later you can always reach editing via the crop symbol on the receipt row.

Drag the **four corners** onto the receipt: „Rectangle“ crops straight, „Trapezoid“ straightens a receipt photographed at an angle. Two sliders adjust brightness and contrast, useful for faded receipts.

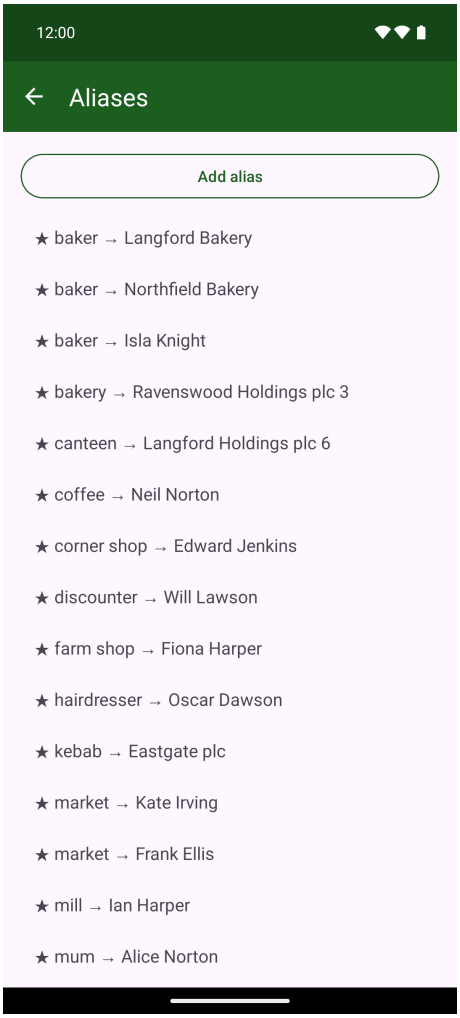

The **unedited original** is always kept – you can start over from it at any time.

Aliases (learned mappings)

If you change the recognized payee while saving, the app offers to remember the mapping as an **alias** – including account, category and place. That way „Mum €100“ is automatically booked to the real name with the right account in future.

An alias can hold **several locations** (e.g. multiple branches) as well as a **„usual amounts“** range that helps guess between several payees at the same place. An alias also remembers tags: they are pre-filled for the next booking to that payee automatically.

Aliases can be created, changed and deleted at any time under *Settings* → *Aliases*.

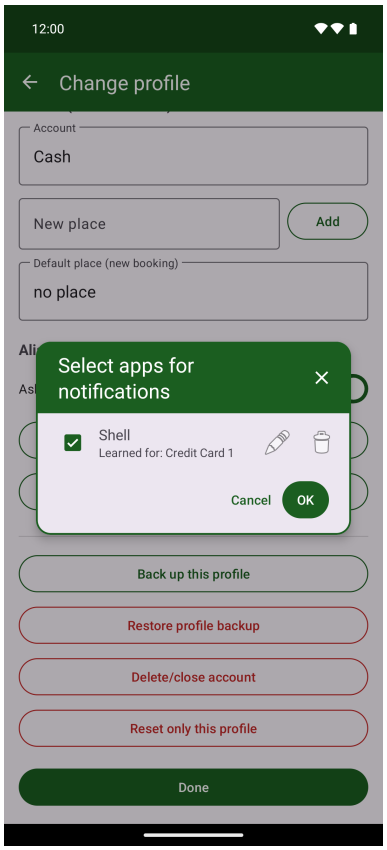

Managing aliases: spoken term → real payee

12. Transactions from notifications

For accounts without FinTS – a credit card, for example: many banking apps report every card payment instantly as a **push notification**. KMySync can read these notifications and suggest bookings from them. There is no built-in list of banks: the app **learns** how your bank's notifications are structured from a booking you enter once by hand.

Turning it on

1. **Turn on the switch.** In **Settings**, turn on **„Transactions from notifications“**. A notice explains what the app keeps; OK opens the system settings – allow KMySync **notification access** there.
2. **Choose the banking app.** Under **Edit profile → „Select apps for notifications“**, tick your banking app. Every app that has already sent a notification with an amount of money is listed. If its notification is still in the notification shade, it is taken over as soon as you tick the app. Each profile chooses its own apps.
3. **Location (optional).** If GPS is on and KMySync has location access **„Allow all the time“**, the app remembers where you were when the notification arrived (see below).

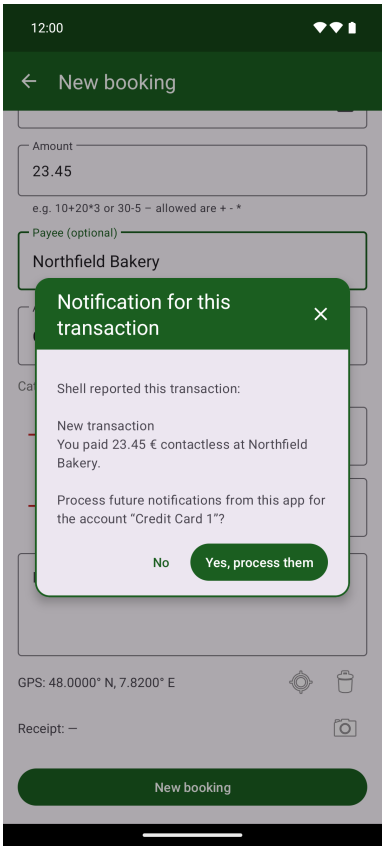

Choosing banking apps per profile

In the list, every app that has already learned something has a **pencil** (edit rules) and a **trash can**. The trash can first deletes the learned rules of that app; once there are none left, another tap deletes the app's stored texts.

Learning: the first notification

When your bank's first notification arrives, enter the booking **by hand** as usual – amount, account, payee. On saving, the app looks for a stored notification with exactly this amount from the time of the booking and asks: **„Process future notifications from this app for the account …?“**

With **„Yes, process them“** it learns a rule: where the amount and the payee are in the notification. If several notifications match, it first asks which one you mean – with date and time, in case two read the same.

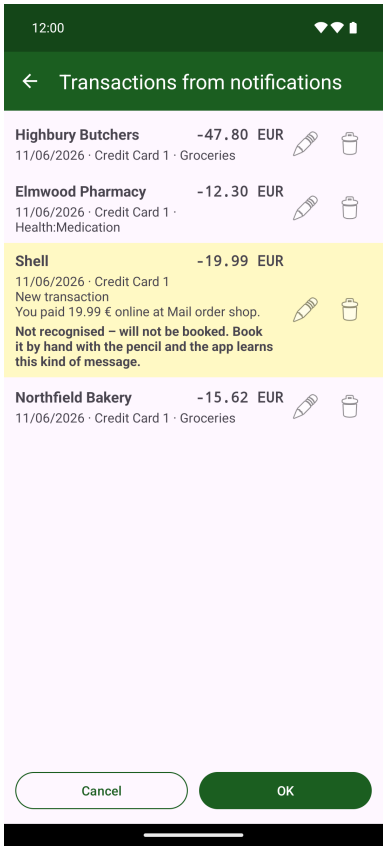

The question after the first booking

After a transfer, the app asks which of the two accounts the notifications belong to: the from-account (money out) or the to-account (money in).

One account, one banking app: if an account learns from a different app, that app's rules replace the account's previous ones. One app may, however, serve several accounts – told apart by the card ending in the notification, for example. For experiments, it is best to use a separate test account.

The list of suggestions on refresh

Suggestions from notifications

When you **refresh all accounts** (pull down or long-press „All accounts“), the app first reads the KMyMoney file and then shows the new notifications as a list – even if the server cannot be reached at the moment. Each row shows payee and amount, with date and account below.

A **transfer** is shown by the arrow in front of the payee: „→“ for money out, „←“ for money in.

- **„Not recognised“** (yellow): no rule fits. The row is not booked. If you fill it in yourself with the pencil, the app learns from it for the next notification of this kind.
- **„Possible duplicate“** (yellow): the account already has a booking with the same amount (up to two days apart), or the same notification is present more than once. It is shown anyway – check it and remove it if needed.
- **Account missing, foreign currency, counter account missing** (red): this row holds up „OK“ until it is completed with the pencil or removed.

The **pencil** opens the booking form with three buttons, all of which lead back to the list: **„Save“** puts your changes into the row, **„Back (without saving)“** leaves it unchanged, **„Delete“** removes it from the list. What you set in the form counts – including the booking type and the accounts of a transfer. If you correct the payee, the app offers to learn the bank's spelling as an alias, just as after dictation. The **trash can** in the row removes it directly.

„OK“ books all bookable rows. Afterwards all notifications shown are done – including the removed and the unrecognised ones. **Cancel** or Back change nothing: the list comes back on the next refresh. If you filled in an unrecognised row yourself, the message after „OK“ says how many new notification variants the app learned from it.

Payee, note and location

The app finds the **payee** exactly as with voice input (Chapter 11): first preferred aliases, then earlier bookings, then the remaining aliases. That is how „MTP Tankstelle“ becomes your „Petrol station“ – with the category of the earlier booking or the alias and, if any, its split. If the payee was last booked as a **transfer**, the list suggests a transfer again, with the counter account used then. Whether it is an expense or income is stated by the notification itself.

The **note** contains the exact wording of the notification – title and text, with line breaks. So KMyMoney later shows what the bank reported.

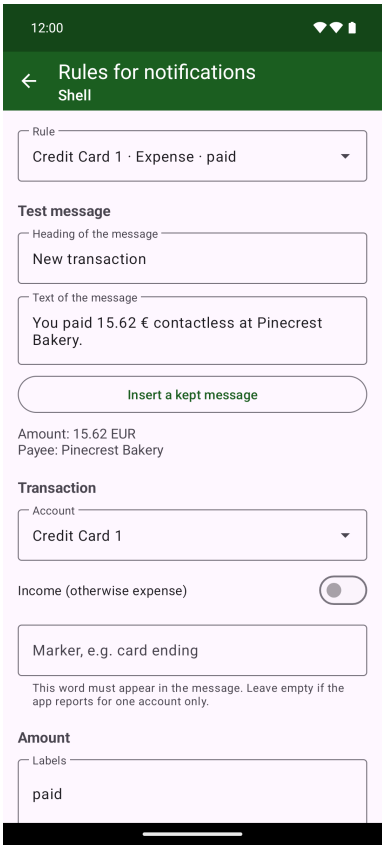

Location: with GPS and „Allow all the time“ access, the app locates the phone for up to **one minute** when the notification arrives and adds the position as a GPS line; it also helps to pick the right branch among payees with the same name. While locating is still running, the notification does not yet appear in the list. Without „all the time“ access the location at refresh is used; with GPS switched off, none at all.

The app recognises **amounts** with two decimals („12.34 €“), and for the chosen apps also whole amounts such as „12 €“ or „1,234 €“ – read according to the profile's number format.

Editing rules

The pencil next to an app opens its **rule page** – laid out like the recognition rules for PDF statements (Chapter 10): a feature such as the card ending, the labels for amount and payee (one per line, further ones are fallbacks), which number is meant and in which currency. At the bottom you can type a **test notification** or insert a stored one; the app shows right away what the rule reads from it.

The learned rules belong to the profile and are part of every backup.

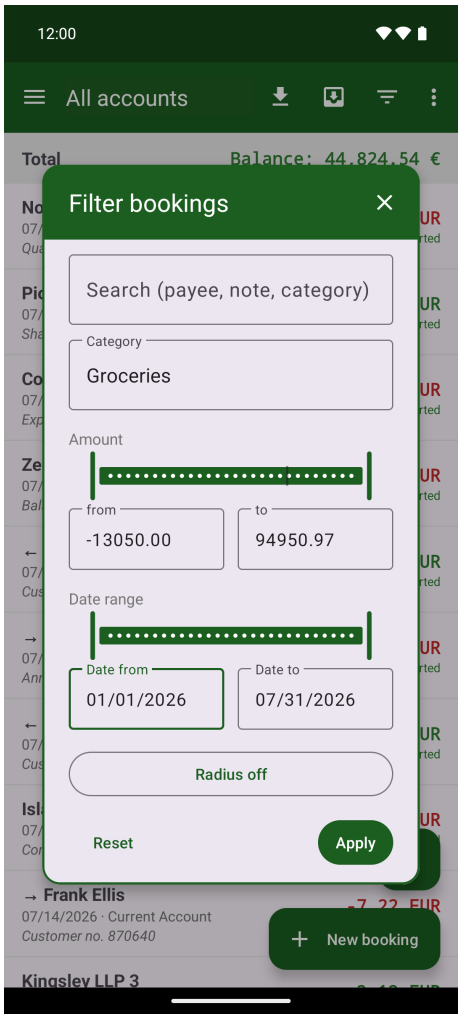

Adjusting a learned rule by hand

What the app keeps

- Only notifications from the **chosen apps** are kept, and only if they mention an amount of money. From other apps KMySync remembers just the name – so they can be offered for selection – and no text.
- The texts are kept in a separate file on the device that is **never part of a backup**. They are deleted as soon as all profiles involved have processed them – at the latest after 24 hours for an app without a rule, after 30 days for an app with a rule.
- Only the wording of a notification that becomes a booking leaves the device – as the note of that booking.

13. Booking list and filter

Filter by search text, category, amount and period

- **Short tap** on a booking opens it as a read-only view: a large coloured heading shows the type (income = green, transfer = yellow, expense = red), and the balance before and after the booking is shown at the bottom.
- **Long press** opens it for editing.
- **Pulling down** re-reads the file in the kmy variant and refreshes exactly this account or portfolio. In the CSV variant this goes through the account drawer (long-press the account).
- **Markers** on a row: „Split“, → / ← for a transfer, „exported“; the colours red and green stand for expense and income.
- The **note** is truncated to two lines in the list; in the editor the field spans four.
- **Undo**: after deleting a booking, „Undo“ appears briefly at the bottom – one tap recreates it. In the place journal the deletion and the recreation stay visible as movements. Transfers have no undo.
- **Long press on the app icon** (home screen): „New booking“ opens the editor directly.

Quick search (tap the account name)

Quick search: Tap the **account name** at the top – it makes room for a search field. What you type narrows the list right away; it searches **payee, note and category** at once, anywhere in the word and regardless of case. The **magnifier on the keyboard** folds the field away again: the account name returns to its place, but the **search stays in effect**. Another tap on the name brings it back for editing – your search word is still in it.

Show everything again: As soon as something is filtered, the line „Filter active (23)“ appears below the account name, with an × in front of it. It clears in **two steps**: the first tap removes the quick search – the line stays and now shows what the funnel alone leaves. The second tap clears that too; the line then disappears and the list is complete again. That way, ending a search does not cost you the period or amount range you set up beforehand. If only one of the two is active, a single tap is of course enough.

The filter (funnel ▽)

The funnel in the title bar narrows the list. At the top sits a **search field** that searches **payee, note and category** at once – anywhere in the word and regardless of case. That way you can find a booking by its note as well. Below it follow category (as a tree), **tag**, amount and **date from–to**. The **magnifier on the keyboard** applies the filter right away – the „Apply“ button sits at the end of this long dialog and thus below the keyboard. If you would rather set an amount or a period as well, just keep scrolling: the keyboard steps aside on its own. The quick search above and this filter apply **together**: set something here, then type up top, and you keep searching within what is already filtered. „Reset“ clears both.

The filter applies to the list and the analysis. With one set, the ⋮ menu also offers **„Export receipts“**, which writes the receipts of exactly that selection into a ZIP file.

Amount and period

For the **amount**, expenses count negative and income positive; the slider runs from the largest expense on the left to the largest income on the right, with a thin mark showing the zero in between. It moves in **shares**, not in amounts: the right thumb at 90 % cuts off the largest tenth – so a single outlier no longer stretches the whole slider. For an exact bound, type it into the field.

The **date** runs as a slider in whole-month steps; type an exact day into the field.

Radius (only with location)

At the bottom – only with **location (GPS)** switched on – sits the **Radius** button. Each tap steps through „off“, 100 m, 500 m, 1 km, 10 km and back to „off“. On a step only those bookings remain that were made within that radius of where you are now.

Where a booking's location comes from: the coordinates in its note, and where those are missing, the learned location of the payee in the alias. Your own position is captured **once** when you apply – so the list does not travel with you as you move on.

If no position is known yet the list stays empty and the title line shows „Filter active (0)“. **„Reset“** restores „Radius off“; after that location no longer matters. Unlike the other criteria the radius applies to the list only, not to the analysis.

Special cases

The **tag** is only present when the app knows tags from the KMyMoney file; „All“ clears the choice again. And with a **category** filter set, a split booking shows only the partial amount of that category.

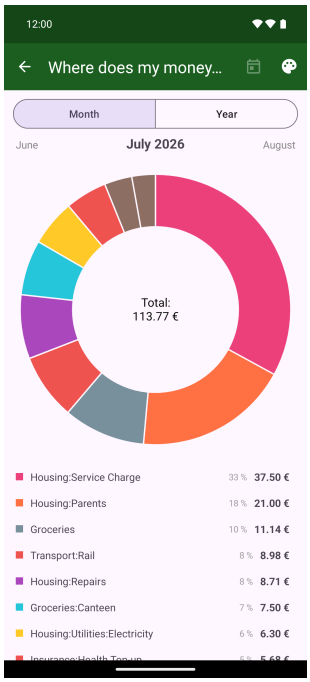

14. Analysis

- Periods: day / week / month / year.
- Views: single account, place or total.
- With an **account group** selected in the drawer, it appears as its own view behind „Total“ and „Total without portfolio“: only the accounts of that group, its portfolios included – the same figure as in the balance bar on the main page.
- **Zoom by gesture**: horizontal = number of bars, vertical = Y axis.
- Closed accounts count only in the total view (historical balance).

Analysis as a bar and line chart

15. Where does my money go?

Category pie chart: „Where does my money go?“

The **Categories** page (menu ⋮ → **Categories**) shows the **expenses per category** – as a pie chart and below it as a list, sorted **descending** by amount. It complements the analysis (Chapter 14), which only shows the development over time per account/place.

- **Month/Year** toggle: current month resp. current year.
- In both views you page through the periods by **swiping** – just like in the budget (right = back, left = forward); the header shows the displayed month resp. year centred and bold, with the previous and next one in grey to the left and right (tapping pages as well). Paging stops before the first booking period and after the current one.
- The chart uses the **full width** and at most **half the screen height**; the list below scrolls on its own while the chart stays visible.
- The slices are unlabelled; a **tap** shows category and amount in the centre, without a selection the total is shown there. The list additionally states the **share in percent**.
- The analysis covers **all accounts** and lists only categories with expenses.
- **Split transactions** count through their partial amounts (not twice), **transfers** are left out – the same data source as the budget page.

Include scheduled transactions (calendar icon)

The **calendar toggle** at the top right adds the **scheduled expenses due** in the period (Chapter 17) to the ones already made – including those that sit as a **deduction inside a scheduled income**, such as the capital gains tax on a dividend. Then:

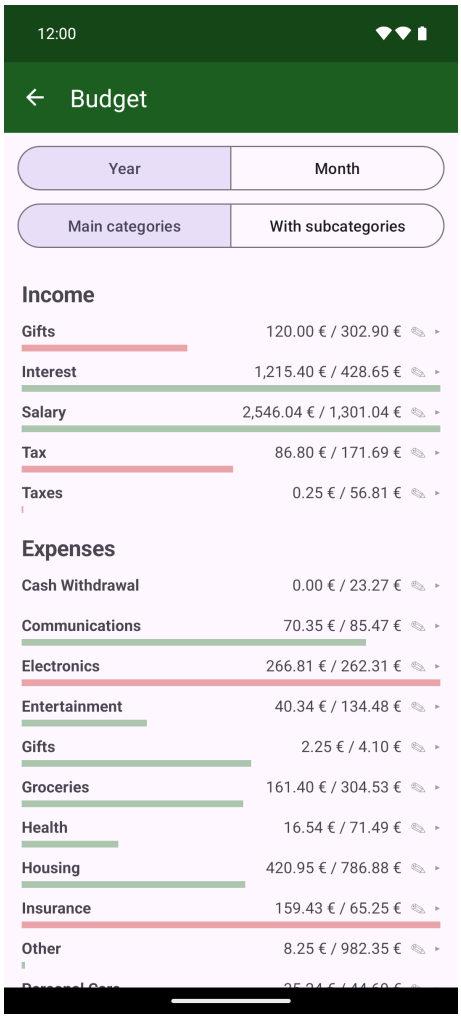

- The **sum per category** grows by the scheduled share; the list sorts by the new sum.
- In the chart the **already paid** share appears in the category's strong colour, the **scheduled** share right next to it in the **same, lighter** shade – together they form **one continuous sector**.
- Rows with a scheduled share can be **expanded** (arrow on the right), showing „Already paid“ and „Scheduled“ separately.
- With the toggle on, the slider also pages into **future** months/years – which then show only scheduled values – up to the last scheduled occurrence.

Set colours (palette icon)

Each category has a **fixed colour** – regardless of its current position in the list. The **palette icon** at the top right opens the colour list: tapping a category opens the picker; „Default“ restores the automatic colour. The assignment takes effect immediately in the chart and list.

16. Budget

The **Budget** page (menu ⋮ → **Budget**) puts the **actual** value against a per-category **target**. It answers the question: „Am I on plan?“

Budget page: actual/target per category, with progress bars

Where does the target come from?

- **Import from KMyMoney** (a button in the settings): if your .kmy contains a budget, its values are taken as the target — **month-accurate** (monthly and month-by-month budgets are stored per month). Such targets are **not editable**.
- **Compute from history**: sum of all previous years ÷ number of years with data. Automatic when the „compute budget internally“ switch is on, otherwise via a button. These targets can be edited by a **long press on a row**.

Whether a category is **income or expense** follows from the .kmy file. A refund therefore reduces the expense category without turning it into income; a computed negative actual is clamped to 0.

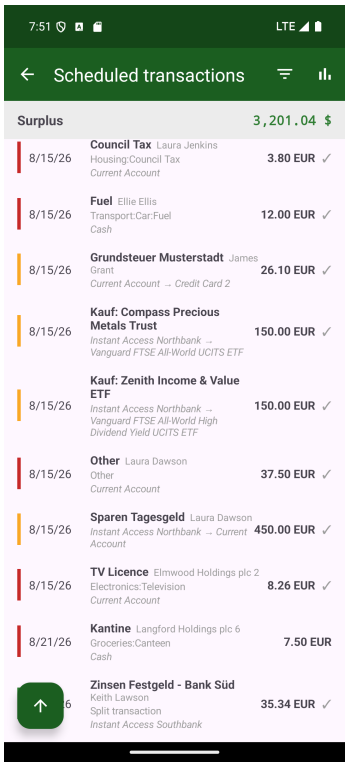

Display

- Toggle **year / month**. The year view sums the months; the month view shows the displayed month's target against that same month's actuals. In month view you page through months with a **swipe** (or by tapping the grey previous/next month in the header).
- Toggle **main categories only / with subcategories** (a main category sums its subcategories).
- **Income** first, then **expenses** (large headers); main categories bold, subcategories indented. The right side shows „actual / target“.
- Under each category a slim **bar**: **green** when on plan, **red** when behind. Its width shows the share of the target used.

When the bar turns green

Instead of a purely linear time comparison, the app learns each category's typical timing from the **payment history**. A **one-time** expense – a transit pass bought at the start of the month, say – is green as soon as it is within budget. **Regular** expenses such as groceries are still measured against the elapsed time. Without history the linear comparison applies; for income it is reversed.

17. Scheduled transactions

Scheduled transactions: chronological list with balance strip

The **Scheduled transactions** page (menu ⋮ → **Scheduled transactions**, shown whenever the app reads from the .kmy; skipping and advancing only in .kmy mode) shows your standing orders from KMyMoney as **one chronological list** by due date. It refreshes only through the **pull-to-refresh** gesture on this page, not with the normal account import.

- **Short tap** on a row: view the schedule.
- **Long press**: book it now.

What the list shows

Each recurring schedule is **expanded into its individual occurrences** – a weekly bakery therefore appears several times, up to **two years** ahead. A coloured strip shows the type: green for deposit, red for payment, yellow for transfer.

Booking or skipping a schedule

A **long press** on a row opens the booking editor as a **new booking**, prefilled from the schedule. Check it, adjust if needed, save with „New booking“. Alternatively the editor offers a **„Skip booking“** button: no transaction is created, but the date still counts as done.

Booked or skipped, the date disappears from the list, and on the next export the KMyMoney schedule moves on to the next due date.

Reminder for due transactions

The switch **„Remind me of due transactions“** in the settings (off by default) reports once a day when something is due; tapping the notification opens this page.

Balance strip (cycling)

At the top, a **balance strip** shows the total for the currently set filter. A tap cycles between surplus/deficit, total deposits, total bills and transfers.

Filter

The **filter icon** at the top right narrows the list, balance strip and chart – by type, account, name/payee and period.

Chart

The **chart icon** at the top right opens an analysis like the account view's: bars per due date (green deposit, red bill) and a development line that starts today at 0 and runs into the future. It inherits the list filter and can be zoomed and panned like the account chart.

Chart of the plans: bars per due date and a development line

18. Synchronizing: performing export and import

The actual sync with KMyMoney runs through **a single symbol** in the main screen's title bar – the **export/sync symbol** (down arrow).

The export/sync symbol in the title bar (circled in red)

Exporting bookings

Tap the export symbol ⬇. The app loads the current .kmy from the sync target, inserts your new bookings, makes a backup first (see below) and writes the file back. Each booking is exported only **once** and then marked „exported“. In CSV mode one CSV file per account is uploaded instead.

Edited bookings. Change a booking that has already been exported and the next export won't add a new one – the existing transaction in the .kmy file is **updated** instead, no duplicate.

When the change does not arrive

If the old transaction is no longer in the file – deleted on the computer, say – the booking stays „edited“; nothing is inserted.

Self-check, comparison and restore

Before the app uploads the new file, it **checks it itself**: whatever it did not mean to touch must be unchanged, character by character; new and changed transactions must be consistent, categories must sit in the right branch (income or expense), and the balance of every account must match the app's bookings. If a check fails, nothing is written and the bookings stay queued for export.

Which lines an export changed

Writing works the way KMyMoney itself does it – line by line, with the attributes in the file's order. After uploading, the app reads the file back from the server and compares. Under **Edit profile → „Changes to the KMyMoney file“** you see, for every export, exactly the lines that changed – for a database, the changed records per table.

If the file arrived **broken** on the server, the app restores the state from before the export; the bookings then stay queued.

(Re-)importing accounts

Import is done selectively via the account drawer (long press):

- **Long press on an account**: imports/updates exactly that account.
- **Long press on „All accounts“** (or pull down): reloads **everything** – accounts, portfolios and scheduled transactions in one go.
- **„Add account“**: fetches an account not yet present from the .kmy, several at once tickable.
- **Long press on the portfolio**: updates securities and prices.

Securities buys and sells are imported as a **transfer** into/out of the security. **Dividends** stay normal income.

Import and export run **in the background** – the interface stays usable, a band shows the progress. If you switch to another app meanwhile, Android throttles the network; the app then waits up to ten minutes until it is in front again instead of aborting. A message only appears on errors.

Backup before every export

Before every write-back the app automatically creates a **timestamped backup** of the .kmy in the „Backup“ subfolder next to the original – a fallback in case something is ever wrong with the file. How many backups are kept is set under **Edit profile → „Backups to keep“** (default 20, 0 = keep all permanently). Independently of that, the first backup of every month is kept forever in the subfolder **„Monthly backups“**.

Protection against overwriting

If somebody works in KMyMoney on the computer while the app exports, their changes must not be lost: if the file changed in the meantime, the export aborts and writes nothing – the bookings stay unexported and can be exported again after a fresh import, without any loss.

KMyMoney open on the computer

The reverse case is one the app cannot always prevent: if the file is open in KMyMoney while the app exports and KMyMoney saves afterwards, it writes its own state over the file – the bookings just transferred are gone, and the app will not send them again. KMyMoney does not check on saving whether the file has changed in the meantime. **So close KMyMoney before exporting** – or reopen the file afterwards before you save there.

From **KMyMoney 5.2** on, the app detects this itself: KMyMoney places a lock file **„filename.lck“** next to the file when opening it, and if the app finds it on the server, the export stops without writing anything. This only works if the lock file actually reaches the server:

- **Nextcloud with the sync client**: only if the client transfers „.lck“ files. The Nextcloud client does so by default; if you have added „*.lck“ to its exclusion list, you lose the protection.
- **SMB share or another WebDAV server**: works as soon as KMyMoney opens the file through a file path – that is, if the shared folder is on the same computer KMyMoney runs on, or if the share is mounted as a drive (network drive on Windows, mounted share on Linux). If KMyMoney opens the file through an address such as „smb://“ or „webdavs://“, it works on a downloaded copy and creates no lock file.
- **KMyMoney before 5.2** creates no lock file; closing it is the only protection.
- If the app reports a lock although KMyMoney is closed, it is left over from a crash. Opening and closing KMyMoney once clears it.

Encrypted KMyMoney files (GPG, SQLCipher)

KMyMoney can encrypt the .kmy file with GPG (**Settings → Configure KMyMoney → Encryption**). The app reads and writes such a file as soon as the matching **private key** is stored in the profile: profile settings, sync connection section below the .kmy path, button **„GPG keys…“**. Without a key, the import tells you which key the file is encrypted to.

- **A separate key for the phone** is the safest choice: KMyMoney can encrypt the file to additional keys as well. Then the main key never sits on the phone, and if the phone is lost, only this one key is revoked.
- **At least export only the subkey** (on the computer): **gpg --list-keys --keyid-format long** shows it in the line „sub … [E]“; then **gpg --export-secret-subkeys --armor <subkey ID>! > phone.asc** – the exclamation mark is part of it. The subkey is enough to read and write the file; the main key, which signs and often opens your e-mail too, stays on the computer. The app also accepts the whole key (**gpg --export-secret-keys**), but warns first.
- **Import**: copy the file to the phone, import it via „GPG keys…“ and enter the passphrase once; the app checks it right away. Then delete the file from the phone again.
- **Further recipients**: if the file is encrypted to several keys, the app writes it back to exactly the same ones. For that it needs the **public** key of each (**gpg --export --armor <ID>**, imported via „Import another“). If one is missing, the app writes nothing – otherwise that recipient, for example KMyMoney on the computer, could no longer open

the file.

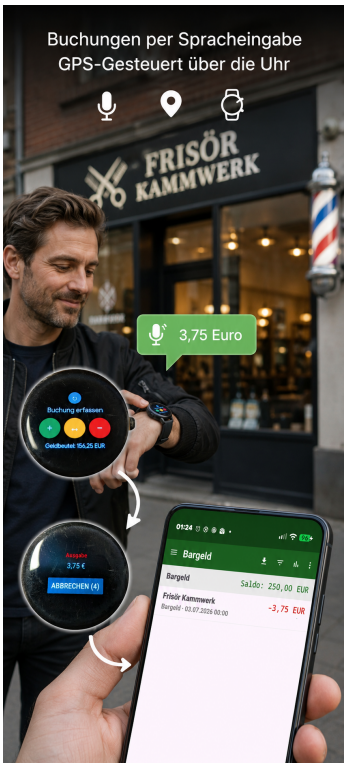

- KMyMoney's **recovery key** („Encrypt with recover key“) is such a further recipient as well; import its public key in the same way if needed.
- **Passphrase**: it is stored encrypted on the device together with the keys (Android keystore), like the server password, and is not asked for on every import. All private keys of a profile need the same passphrase. To protect the phone further, switch on the **biometric lock** (Security & privacy).
- The keys are not part of any backup; after changing devices, import them again.
- **KMyMoney database instead of .kmy**: KMyMoney encrypts a database not with GPG but with a **password** (choose the „SQLCipher“ driver when creating it). Store the password via „Database password…“; it is kept encrypted on the device as well. The next import shows whether it is correct.

GPG and SQLCipher protect the file on the server and in its backups. After the import, the transactions are stored **unencrypted** in the app; there they are protected by the phone's screen lock. In addition, the app's **biometric lock** is recommended (Security & privacy).

19. Wear OS (watch)

With the watch app you record a booking by **voice** or by **digits** right on your wrist. The watch captures amount and payee; the booking itself is created on the phone.

- **Three type buttons**: income (green), transfer (yellow), expense (red). A tap starts voice entry.
- **Amount by digits**: the digits symbol opens a number pad – for recording silently, e.g. in a meeting.
- **Tile**: the same three buttons plus the balance are available as a Wear tile; it shows a preview in the watch's tile picker.
- **Default-place balance**: shown below the buttons, e.g. „Wallet: €70.00“.
- **Offline**: bookings not yet transmitted are delivered automatically once the phone is reachable.

Recording on the watch

Requirements

The watch app needs the watch's Google services (Wear Data Layer). It is therefore only available together with the full version from the **GitHub releases**, not via F-Droid. Phone and watch app must share the same signature (same key) – which is the case when both come from the same release.

Speaking

After tapping a type button the watch first shows „One moment…“. Only when it **vibrates** briefly and shows „Speak now…“ is it listening – say payee and amount, e.g. „Barber 20 euros“. If recognition heard nothing at all on the first attempt, the watch silently tries once more by itself. If it does not understand the sentence, „Not recognized“ appears; just tap the type button again.

Confirming amount and payee

Confirmation page: amount, payee, „Next payee“ and „Cancel“ with countdown

Voice and digit entry end on the same confirmation page: the amount at the top, below it the payee, a grey **„Next payee“** button and **„Cancel“** with a countdown.

- A **spoken payee** comes first and stays the default as long as you change nothing.
- It is followed by the **payees within 100 m**, nearest first – in the same order as on the phone (preferred aliases first) and matching the selected account. This works even without the phone nearby, because the list is stored on the watch.
- **„no payee“** books deliberately without a payee; the phone then does not look for one either.
- After **10 seconds** without a change the booking is made; every payee change restarts the countdown. Simply leaving the page also books. „Cancel“ or the back gesture discard the entry.

Switching account and place

Above „Record booking“ the grey **„Switch account/place“** button cycles through the shown account; the next booking then targets that account. After one minute the selection reverts to the default place by itself.

When a reason appears instead of the balance

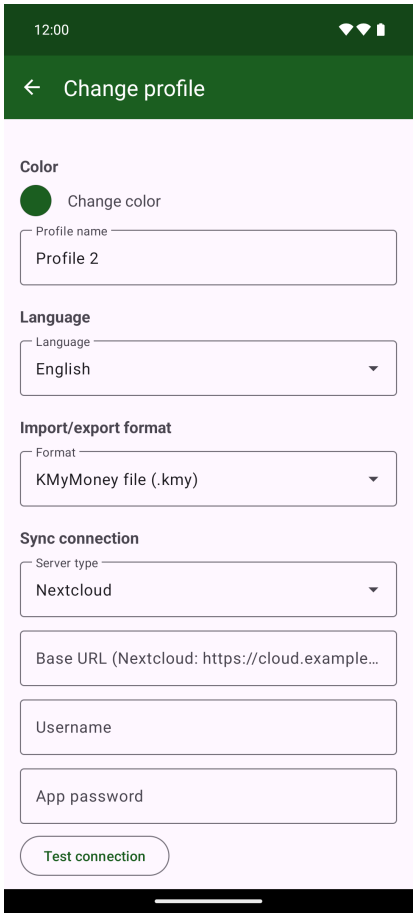

While bookings are **not yet transferred**, the place of the balance shows how many are pending and why: „2 pending · GPS“ (the watch is still waiting for a location), „1 pending · No phone“ or „… · sending…“. As soon as everything has reached the phone, the balance is back.

Recording offline (phone off or disconnected)

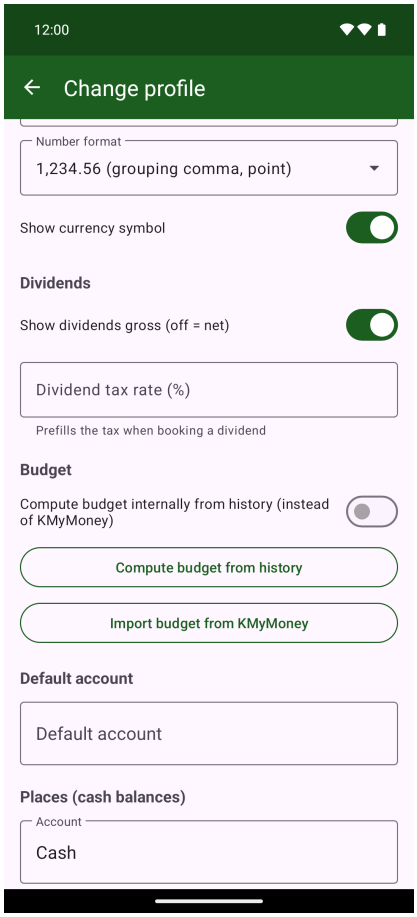

Speech recognition also works without the phone and network, provided an **offline speech model** is present on the watch. On the phone, the setting „Install offline speech package on the watch“ downloads it once; on some watches it must additionally be enabled under System → Languages & input. If recognition really has no connection, the watch opens the number pad („Offline – enter amount“): type the amount, pick the payee as above, and the booking is sent once the phone is available again.

20. Settings (complete reference)

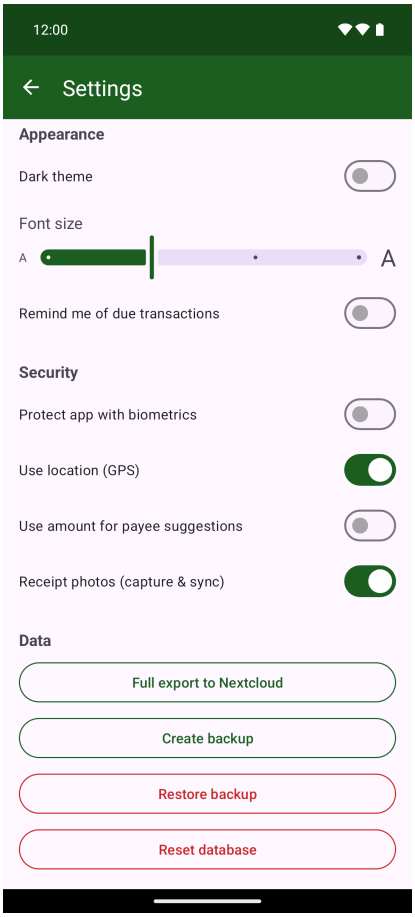

The settings are reached via the ⋮ **menu** at the top right – entry **„Settings“** at the very bottom. On first start the welcome assistant (Chapter 3) already sets the essentials; here all fields are described in screen order. Changes take effect on **„Save“** (language and dark mode immediately).

Change profile: colour, language, format, server connection

Change profile: number format, dividends, budget, default account, places

Appearance, security, data

Language, number format and currency

- **Language**: German/English (more via a language file). Pre-selected from the phone on first start; the choice takes effect immediately. Via **„Export/upload language template“** you can maintain your own translation as a file.
- **Currency**: default currency symbol for accounts without their own currency (taken per account from the file on .kmy import).
- **Number format**: „1.234,56“, „1,234.56“ or „1234,56“/„1234.56“ without grouping; plus the **„Show currency symbol“** toggle. Applies to all amounts in the app and on the watch; the export keeps a stable format.
- **Dividends gross/net**: whether portfolio dividends are settled gross (declared) or net.
- **Read statements**: allows reading the bank's PDF statements in the portfolio (default: off). When switched on the app states how many banks the recognition was measured against. The complete documentation is in Chapter 10.
- **Budget in-app**: compute the budget actuals from history instead of importing from KMyMoney (see Chapter 16).

- **Install offline speech package on the watch** (GitHub build with the Wear bridge only): lets the watch download the offline speech model of the chosen language so voice recording works offline too (see Chapter 19). Off → the number-pad fallback applies offline.

Date format: dates in the app follow the chosen language – „DD.MM.YYYY“ in German, the customary notation in English and Spanish. If the chosen language matches the language of the device, its *country* counts as well: English is written „MM/DD/YYYY“ in the USA but „DD/MM/YYYY“ in the UK. There is no separate setting for this because the device already answers the question. The **CSV export is unaffected** and still writes „DD.MM.YYYY“ – it follows the file, not the display.

Connection to your server (SMB / WebDAV / Nextcloud / local folder)

The most important setup step, so the app can exchange data with KMyMoney. Choose the **server type** and enter the access:

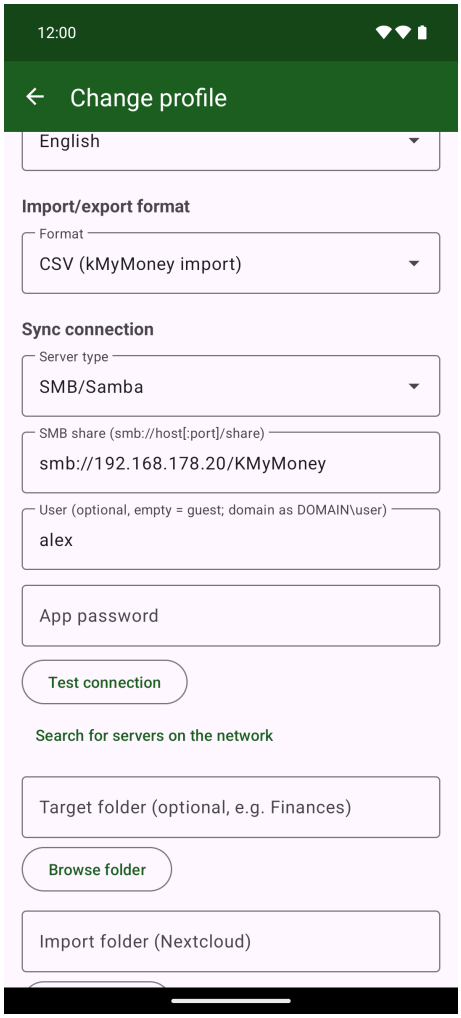

- **Nextcloud**: base URL of the server + app password (Nextcloud → Security → App password).
- **WebDAV (generic)**: full DAV root URL, auth via HTTP basic.
- **SMB/Samba**: set up through a **wizard** – see below. SMB2/3.
- **Local folder (on this device)**: no server. **„Choose folder…“** opens Android's folder picker; in it you choose the KMyMoney file as usual. Meant for a folder that a sync app such as Syncthing keeps in step with the computer. Export, backups and receipts work there just the same, and „Test connection“ checks the access grant, reading and writing.
- **„Test connection“** checks more than the credentials: the whole chain up to the write permission – see below.

Receipt folder: the folder next to the KMyMoney file that holds the receipt photos – „Receipts“ by default for a profile set up in English (profiles from before version 2.5 keep „Belege“); if several profiles keep their file in the same folder, give each one its own name, otherwise each profile would take the other’s receipts for orphaned.

Setting up SMB/Samba (wizard)

With server type **SMB/Samba** a wizard replaces the address fields, so you don't have to remember host or share names:

1. **Search for servers.** On opening, the app scans the local network automatically. Each hit is listed with its display name and IP address; **„Search again“** restarts the scan.
2. **Log in.** Enter username and password of the server. The password is stored encrypted and never shown in clear text.
3. **Pick the share.** The app reads the server's shares; clicking one fills the **„Share name“** field.
4. **Save.** This becomes the address „smb://host/share“. The **target folder** inside it is then chosen with „Browse folder“ or „Choose .kmy“.

SMB connection by hand; „Search for servers on the network“ starts the wizard

When the server does not listen on port 445

A share without a password

An empty user means guest. For a share without a password simply leave the password field empty – the app then continues as guest, even with a user name filled in.

Above the login fields sits a **„Port“** field. Leave it empty as long as the server uses the usual SMB port 445. If it announces a different one over Bonjour, that port is already filled in; if nothing answers there, the app also tries the default port 445 and corrects the stored address. The address then reads „smb://host:7777/share“.

Further details

The scan runs three ways at once: Bonjour/mDNS, a NetBIOS name query and a connection test on the SMB port. The servers found last time are remembered and shown right away when you open it again.

If the server belongs to a **workgroup** other than „WORKGROUP“, the field is already pre-filled – the search names it below the server name whenever the server reports one. If it refuses to list its shares either, type the share name by hand; system shares such as IPC$ are hidden anyway.

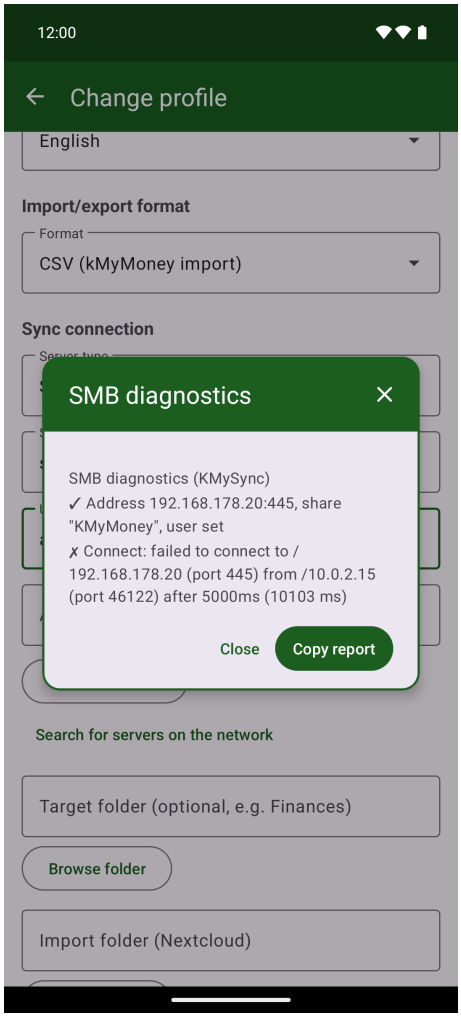

„Enter server manually“ brings back the classic fields for typing the address yourself. **„Search for servers on the network“** returns to the wizard at any time.

Workgroup or Windows domain: at home the workgroup is usually called „WORKGROUP“ – it plays no role for signing in, Samba servers and NAS boxes only check user and password. It is different in a real **Windows domain (Active Directory)**: there you enter the user as

DOMAIN\user (or as „user@domain.local“). Without the domain the login may fail with „Username or password is invalid“ even though the password is correct. For a Windows PC with a local account, „COMPUTERNAME\user“ helps.

If something fails, the wizard names the reason: „Server not reachable“, „Username or password is invalid“, „The selected share is not available“ or „Access to the folder was denied“ – followed, in brackets, by the server's **raw status code**, so a report can actually be traced. „Server not reachable“ only ever appears while no connection has been established yet. If the port field does not hold a number between 1 and 65535, it says so right away without trying to connect.

Test connection

The report: every step with its result – here the connection already fails

The button **„Test connection“** – in the settings **and** in the first-start wizard, for **every** server type – checks far more than the credentials. It walks the whole chain, right up to the question that matters in the end: may the app **write**, **rename** and **delete** in this folder?

What you see while it runs

A check takes a few seconds, and when something really is wrong, every single step first waits out its timeout. That is why a **yellow band** appears below the button: on the left the step that finished last, with a green check or a red cross, on the right the one currently running. So you can always see how far it got and what it is working on – instead of a screen that simply sits still.

When everything works

Then one sentence is enough: **„Connection successful“**. If you want the details anyway, **„Show report“** opens the full list.

When something is wrong

Then the **report appears right away**: for every step whether it worked, how long it took and, on failure, the **raw status code** – plus, where possible, what it means. An „HTTP 401“, for instance, names the most common cause straight away: with two-factor authentication switched on, this field needs an **app password**, not the account password.

„Copy report“ puts the result on the clipboard – meant for sending along with a bug report. The report contains **neither the password nor the user name**: the user appears only as „set“ or „empty“, and in the Nextcloud address as „<user>“. Server, port and path layout

are in there in plain text – without them nobody could help you from a distance.

The steps for SMB/Samba

The whole chain runs in **one** login – just as normal operation does:

- **Connect** (noting it if the default port was used instead of the configured one),
- **Negotiate**: which SMB dialect, whether the server requires signing and whether encryption was negotiated,
- **Log in**: as a user or as guest, encrypted or not,
- **Read shares**, **open share**, **read folder**,
- **Write**, **rename** and **clean up** in the folder – using a tiny test file that disappears again right away,
- **Check the file** and, if it exists, whether it is **writable** (.kmy mode only).

The steps for Nextcloud and WebDAV

- **Address**: how the app reads your server address. This is also where the most common typo shows up – if with server type „Nextcloud“ the path „/remote.php/dav/…“ is already part of the base URL, it would end up in there twice.
- **Reachability**: whether anybody answers there at all, and whether they **speak WebDAV**. If you accidentally entered the address of the web interface, it says so here.
- **Redirect**: where the server forwards you, if it does (from „http“ to „https“, say).
- **Log in**: user and password. A refused login is told apart by reason – wrong credentials, a protective layer in front of the server, or a wrong address are different things.
- **Read folder**, then **write**, **rename** and **clean up** in it,
- **Check the file** with its size, and the **version tag (ETag)** – if the server supplies none, the app cannot tell when writing back whether somebody else changed the file in the meantime (.kmy mode only).

Why renaming and deleting are part of it

When transferring, the app first writes your KMyMoney file **in full** under a temporary name and only then has it put in place – that is the only way an interruption (a dead spot, a timeout) cannot half-overwrite your file and leave it unreadable. The folder needs all three permissions for that. A folder where creating and deleting work but renaming does not would otherwise only surface on the first real transfer – that is, after you have already recorded bookings.

Export mode

- **.kmy mode**: writes new bookings straight into the KMyMoney file (including splits and transfers) and imports accounts/bookings as well as the portfolio from it. **„Choose .kmy“** opens a file browser (subfolders, „..“ to go back).
- **CSV mode**: exports one CSV file per account (each booking only once); the target folder and import folder are set here.
- **Read .kmy, export CSV**: accounts, categories, payees, schedules and portfolio come from the KMyMoney file, but the app never writes to it – new bookings go out via CSV and are imported in KMyMoney. For anyone who does not want the app to write their .kmy.
- **KMyMoney database (SQLite)**: like .kmy mode, but for a KMyMoney database in SQLite format instead of the .kmy file. Supported are the databases of KMyMoney 5.1 and 5.2 (schema versions 12 to 16), including ones encrypted with SQLCipher: then store the password via the button **„Database password…“** below the path. Open and save an

older database once in a current KMyMoney; a database from a newer KMyMoney version is read by the app, but nothing is written into it. If KMyMoney currently has the database open, the app writes nothing.

- **Read SQLite database, export CSV**: the counterpart of „Read .kmy, export CSV“ for the database.

Restrictions whenever writing via CSV (CSV mode and „Read .kmy, export CSV“): exported bookings can no longer be changed or deleted (only used as a template for a new one), split bookings cannot be created, schedules are not advanced, and nothing can be entered in the portfolio. The corresponding buttons are simply absent – a CSV file can only carry new bookings.

Two quirks of „Read .kmy, export CSV“: bookings exported via CSV disappear from the app on the next .kmy read until you have imported the CSV in KMyMoney and saved the file – they are not lost, they are in the CSV file; please do not enter them a second time. And a payment booked from a schedule leaves the schedule due in the app until you have entered it in KMyMoney.

Switching away from .kmy mode: if deletions, advanced schedules, portfolio entries or changed bookings are still waiting to be transferred, the app asks first. „Discard and switch“ removes these pending items (portfolio entries together with their money booking); changed bookings then count as exported so they do not go out twice via CSV. If you do not want that, transfer once more in .kmy mode first.

In CSV mode, without a sync target the app exports into a folder you choose. The .kmy mode, by contrast, always needs a sync target, because the app reads the file and writes it back – a local folder on the device is enough for that. How the sync runs is in Chapter 18.

Default account and places

- **Default account**: pre-selection for new bookings (also for widget and watch). Selectable only once accounts exist.
- **Places per account**: per account you can create cash **places** and set a **default place** (see Chapter 8).

Alias names

The **„Prompt“** toggle controls whether the app offers to learn an unknown payee as an alias after you speak (existing aliases still apply). Via **„Manage alias names“** you create, edit and delete aliases by hand – with spoken term, real payee, booking type, account, categories and location (via **„Open map“** on an OpenStreetMap map). The **„prefer“** toggle (★) puts an alias ahead of the booking search; the same term may point to several payees distinguished by location.

Transactions from notifications

The switch **„Transactions from notifications“** applies to the whole device; which banking apps are read is set by each profile under **Edit profile → „Select apps for notifications“**. Everything else is in Chapter 12.

Appearance

- **Dark mode**: light/dark (takes effect immediately).
- **Reminder for scheduled bookings**: reminds once a day of scheduled bookings due today (off by default; see Chapter 17).

Security & privacy

- **App lock**: optional via biometrics/device credential (fingerprint, face, PIN, pattern, password) – on start and when returning from the background. When the app hands over to another app itself – camera, gallery, file picker, speech input – returning within five minutes does not ask again. Stay away longer and the lock is back.
- **Location (GPS)** switch (default **off**): controls all location use. Off = no permission prompt, no GPS note, no amount-only entry, no alias location. The position is used locally only, never sent to a service.
- **Use amount for payee suggestions** (default **off**): on = the amount helps decide where several payees share a location – in the number pad the name shown changes with the amount, and the booking editor pre-fills an unambiguous payee. Off = both stay quiet; the number pad shows the nearest payee, which you change by tapping. **Regardless** of this switch, plain **voice entry without a payee** – on the phone as from the watch – always uses the amount, because there is nothing to choose there.

Data

- **Export all** and **Create/restore backup** (see below).
- **Manage accounts (delete/close)**: a **multi-select** lists all accounts with status (Active/Closed). The bottom row has (context-dependent) **Close/Reopen** and, on the right, **Delete**; **Close** only at balance 0, **Reopen** only for closed accounts. A closed account no longer appears anywhere – only in the total analysis view does its historical balance still count.
- **Reset data**: deletes the local database (a fresh start like the first time – the welcome assistant appears again afterwards).

Creating and restoring a backup

„Create backup“ writes **data and settings** into a ZIP file: the database (bookings, accounts, place journal, portfolio, schedules) *and* all settings – including the places per account, the category colours and the server access. Beforehand the app asks two things:

- **Include the server password? No** by default – then the password appears nowhere in the file and is entered once after restoring.
- **Backup password** (optional, entered twice): it encrypts the **whole file** (AES-256-GCM, file extension *.abk* instead of *.zip*). Without a password it stays a plain ZIP.

On **„Restore backup“** the app first asks for the backup password if needed, and then **what** should come back: **data only**, **settings only** or **both**. That way a broken configuration can be repaired without touching the recorded bookings. The app restarts afterwards. Receipt photos are not part of the backup – once uploaded they live on the server.

When switching devices this backup is the only way. Android does **not** include this app’s data in its own backup – neither in the cloud nor when transferring to a new device. That is deliberate: bookings, receipts and the server access should leave this device only for where you send them yourself. So create a backup *before* the switch and restore it on the new device.

News

After an update, the app shows the dialog **„New in version …“** once on the first start, listing the new features of that version – only real new features, no bug fixes. If a version brings only fixes, nothing appears, nor after a fresh install. **„All news“** in the dialog or the **„News“** button at the very bottom of the settings opens a page with the new features of all previous versions, newest first.

21. CSV format (export)

German locale: column separator „;“, decimal separator „,“, date DD.MM.YYYY, UTF-8. Exactly one category per booking – there are no split bookings when writing via CSV (see chapter „Split booking“).

```
Datum;Empfänger;Konto;Typ;Betrag;Notiz;Kategorie
29.06.2026;Metzgerei;Bargeld;Ausgabe;-7,30;Mittagessen;Lebensmittel
```

No guarantee for every bank: this recognition works with general rules rather than code written specifically for each institution – a fully tailored recognition for every bank would need its own code per bank, the way professional payment apps with a dedicated team can offer. As a one-person project, this app cannot provide that. With unusually structured statements the recognition can therefore fail or suggest wrong values – always check the suggested values before saving.

22. Disclaimer

This app is provided as-is, with no warranty. In particular, there is no guarantee that the .kmy file remains fully valid after an export. Thanks to the automatic backup before every export, however, you always have a fallback. Keep your own regular backups as well.
